# THE BUILDING NEWS

## AND ENGINEERING JOURNAL.

### ARCHITECTURAL SPECIALITIES.

**P**ERIODICAL reviews of the progress made in technical details and decorative accessories are necessary to the architect, and in commencing a new year it may be of interest to call attention to some of the improved appliances of value to the builder and architect. Many of these are not altogether new, others are improvements upon old systems, or are revivals of old arts and industries. For the purpose of grouping and classification, we may consider the specialities of building and architecture under those heads into which all buildings may be divided—namely, walls, floors, ceilings, roofs, chimneys, decoration. Under the structural head of walls, a variety of materials may be noticed. Bricks and terracotta occupy an important place, to say nothing of stone. To confine ourselves to the two first materials, we must admit that very considerable improvements have been effected in brick manufacture of late years, owing to improved kilns and appliances, to which we need not here refer. The modifications made in kilns for burning bricks are as varied as the kind of bricks produced. The architect looks to the result more than the means; he likes his bricks to be evenly burnt, and of fairly uniform colour, though the latter is not always to be desired from an artistic point of view. To grind the clay dry, mix it thoroughly with sand, and then press it, is the formula we gave some years ago for good manufacture. Several firms now turn out excellent bricks in red, white, buff, and other tints. Such are those manufactured by the Hathern Station Brick Company, the Suffolk wire-cut bricks of the Woolpit Brick Co., the white facing-bricks made at Aylesford, near Maidstone, and other sorts. The gault clay makes a heavy brick, to lessen the weight of which perforations are introduced, or a "frog" is formed, as in the last named; but this material has the merit of being very hard and durable, and of good colour. The famed Suffolk bricks are of the gault clay, so are the patent bricks made near Hitchin. Architectural effect now is obtained in many ways; white and red rubbers, hand made, moulded bricks, and terracotta, are used. The Bracknell T.L.B. rubbers are well known, and the sand-faced hand-made facing-bricks made at Bracknell are equal to any. Many manufacturers supply facing-bricks of uniform colour, hard, and well burnt, and others in two shades of red, as a red and pink, or red and puce coloured. The moulded and pressed bricks are made in a variety of patterns, and moulded to shapes suited to any situation. Terracotta has advanced to a high state of perfection. We can point to the excellent terracotta supplied by Messrs. Gibbs and Canning for the Natural History Museum, and other buildings by Mr. Alfred Waterhouse, R.A.; the red and buff

coloured material manufactured by J. C. Edwards, of Ruabon, to show how the uncertain shrinkage of the clay has been overcome by dexterous admixture with other clays, or ingredients like glass and sand, and by careful drying. Recent improvements have been made in the baking and patterns, so that large blocks and castings are produced, which a few years ago would have been impossible. Nor can we dismiss these materials without reminding the reader of the vast variety of clay-made appliances, and what a large part they play in building; bricks and terracotta are now used for arch voussoirs to suit any curve, hollow bricks for building walls, for fire-proof partitions and floors, perforated air bricks, pavings, copings, plinths, strings, and cornices. Confining our attention to the wall, we may point to the value of this material when specially prepared for templates and seatings for beams, the value of the damp-proof course, as manufactured by the Broomhall Company, besides the other materials, such as Claridge's patent asphalt, which can be employed in a number of ways to walls not only to prevent damp rising, but to check damp descending, to line basement walls and reservoirs. In wall construction various specialities have been introduced; we have "breeze" or concrete bricks, wood bricks for fixing joinery work, cramps for tying together hollow walls. Several patent inventions for constructing hollow walls have been before the profession, though they have not met with the encouragement which the ingenuity of their inventors has deserved.

Under the generic head of Floor, are naturally suggested various kinds of improved flooring. In brick and tile floorings there is nothing very new to mention; but the architect of large and public buildings is now of necessity obliged to lay his vestibules and corridors in a hard and durable material, either of real marble or in some form of artificial stone or "mosaic," of which the "marble mosaic pavement" is the highest form, such as that laid by Burke and Co. Encaustic tile pavements will always maintain their position as an architectural decoration, and the Messrs. Minton's (Stoke-upon-Trent) tiles, the Godwin tiles, the Ruabon, and other Staffordshire tiles are favourably known for their truth, pattern, and colour. Next in architectural value come the various kinds of wood floorings, such as block flooring and parquet, and other modifications having the peculiarities of each of these kinds. Of wood-block floors their name is legion; two or three varieties deserve to be remembered by architects in specifying. One of the oldest and best is Lowe's improved system, in which the blocks are thick and laid in various ways, such as the herring-bone pattern found in many school floors, churches, drill-halls, and basement floors, in which each block is

secured to a concrete bed by a patent composition which prevents "dry rot" or the permeation of moisture. We have described this system on several occasions. A parquet effect can be given to this sort of floor in the more ornamental patterns. In another kind the blocks are also laid on an adhesive composition upon cement concrete; but the blocks are secured to each other by means of dowel pins, and the fixing is effected by dovetailed sleepers let into the concrete, and by grooves at the bottom edge of each block. Such is Duffy's "Immovable Acme" system, which has been largely employed. In a recently-introduced system—the "Westminster Patent Flooring Company"—each block is keyed to six other blocks, and the whole is fixed to a concrete bed at intervals. The keys are small discs of metal, which are inserted in grooves at the corners of each block. Various ornamental hardwoods are used, and the patterns can be varied, as any sized blocks can be used, and the system appears to be specially suitable for thin floors. The "Pavodilos" is now a recognised improvement in flooring of a superior character, on which the secret nailing is required, and as a fancy floor it is of less cost than parquet. Parquet floors of the more ornamental kinds enter largely into new buildings, and as they can be applied to old as well as floors, they are a valuable accessory new to decorative effect. The improved machinery and modes of manufacture have contributed to render parquetry, whether as floors, dadoes, or wall linings, a very durable and inexpensive kind of interior decoration.

The ceiling has been the object of a great many improved modes of decoration and not a few plasters. One of the most recent is that known as the "Adamant" plaster, a material now used by many leading architects and builders. Its advantages are that it does not fall, crack, nor shrink, and the walls and ceilings on which it is used present a hard and durable surface for decoration. This plaster can resist almost any kind of injurious action, and it can be applied before the building is quite dried. In this connection we may refer to "Anaglypta," a material now largely employed for ceiling and wall decoration, in which a low relief is obtainable. Few decorative materials can surpass this for ceilings, in which the depth and relief of plaster or wood is not desired. We have lately seen it applied with good effect in the vestibule, ceilings, and rooms in Baker-street, by Messrs. Campbell, Smith, and Co., and its cheapness is in its favour. The readiness with which it can be applied and its extreme lightness and ornamental effect make it a useful decoration for old buildings.

Under Roofs, we may notice improvements in coverings; but we wish rather to note the

modifications that have been introduced in the form of ventilating expedients. Boyle's air-pump ventilators have overcome the prejudices of architects to ventilating appliances on ridges and other conspicuous parts of buildings. The varied types of roof ventilators now made, based on the only efficient pneumatic principle of inducing an air current or vacuum, make it possible for architects to specify a system of ventilation. Whether it be the turret form, the ridge form, or the concealed-roof ventilator, the architect can have no valid excuse for omitting a means of escape for the vitiated air. In this latter class we must place the "Honeyman" system, in which a horizontal tube is carried through the roof transversely in connection with an upright tube, the horizontal current of air from the openings in the roof creating a vacuum in the top of the inner vertical tube, and drawing out the vitiated air in the latter, which escapes on the leeward side of roof. Improved means of adjusting skylights may be named, but we can only mention the various kinds of lever, rack, and pinion adjustment, or a cogged rack actuated by a screw and pulley, as in Leggott's patent. Improvements in glazing roofs are numerous, of which Rendle's system may be mentioned as being one of those largely employed.

The chimney has been long the subject of quack doctoring in various shapes. The most important desideratum is a mode of constructing a stack of several flues so that they may occupy a small compass above the roof. The ordinary brick "with" takes up a large space; but by introducing fire-clay tubes or iron pipes, economy is secured in the building of stacks. Messrs. Doulton are manufacturers of combined smoke-and-air flues to be built into chimney breasts. A great deal of unnecessary room can be saved by introducing this kind of tubular flues, and in outside stacks cast-iron socketed flues are built within the outside brick case of the stack. The French are ahead of us in chimney construction, and the French chimney-builder can erect stacks of great height and perfectly true. Of chimney cowl and appliances for preventing smoke, the simplest forms of inducing an up-draught are undoubtedly the best, and many ventilating firms make cowls for this purpose or preventing a blow-down.

We can only very briefly touch on the large and increasing number of general building appliances. Of mechanical appliances, the lift is an important item in the fitting up of modern buildings. Such firms as R. Waygood and Co. have made it a speciality of manufacture. Then we have a host of structural appliances and ironwork, such as Dennett's fireproof floors and constructive ironwork for preventing the spread of fire, which are being used very extensively in modern buildings; iron staircases, and treads for stairs, such as Hawksley's, patent semi-prism lights for lighting basements, as those of Hayward's, electric lighting appliances and fittings, a new branch of internal fittings which promises to develop into a large and lucrative business, all kinds of ventilating gas appliances, heating stoves and apparatus, and numerous sash fasteners, casements and water-bars, asbestos paints, such as Bell's Aquol paints, fire resisting and washable, and a catalogue of builders' ironmongery and sanitary apparatus. The field covered by these specialities is so large that it would take a volume to simply describe them. Heating and ventilating patents and inventions alone make up a very important branch of these specialities. The architect, no less than the builder, has to master the technical merits of these inventions, for the purpose of specifying them; he has further to make himself master of the principles on which they are made, to discover how far they answer the objects they are intended to serve, and to

introduce them in his design in the most desirable manner. With respect to decorative woodwork and materials, which we have barely found space to notice, the architect's functions in specifying are no less onerous. He must see that the wall linings, the parquet floors, the modelled plasterwork, and the fittings of an ornamental character are in correct taste and not offensively introduced.

#### IMPROVEMENT SCHEMES AND BUILDING LEGISLATION.

THESE are now the order of the day. We have plans for widening thoroughfares, removing obstructions, forming public parks, making subways, in all of which alterations the architect is much concerned, and it may be personally interested. Several Bills have been prepared and sanctioned by the London County Council for various Metropolitan schemes. The principal of these deals with the proposed Strand Improvement; a General Purposes Bill includes several schemes—one for the removal and reconstruction of Barking-bridge, for the purchase of Brockwell Park, for the construction of subways, for the removal of bars between Euston-road and the south, and other matters. In all these schemes we may be sure the architect, engineer, and builder, and a large train of skilled experts will find employment, and therefore we may hail these measures as auguries of good for the New Year. Whether they will actually turn out to be improvements will depend on various circumstances. The Strand Improvement is an important question, though it affects only a few people directly, its main object being the removal of the block of houses between Holywell-street and the Strand, and the improvement of the locality on the north side of that thoroughfare. The block which now divides a portion of the Strand into two streets has long been a disfigurement, and as it now stands there can be little said for its continuance, save that it contains two or three very interesting remains of Old London houses of the last century, and that it has been from time immemorial a favourite haunt of book collectors and curiosos. Shut off from the noise and bustle of the traffic of the Strand, Holywell-street has enjoyed a kind of literary immunity of its own, and many prefer to saunter through its narrow street for a few yards to enjoy the comparative quiet of its precincts. But these by-ways and nooks of Old London are, we are afraid, doomed to disappear before the march of progress and reform. The chief question is, Will the widening at this point be an unqualified improvement? There is undoubtedly a too narrow roadway and a very inadequate foot pavement along the Strand at this part; but the addition of another 15ft. to 20ft. would make a very considerable difference. Beyond this, the widening would be injudicious, unless the space now occupied by the obstruction were converted into a green plot of grass or a pavement. The Bill proposes to deal with the locality to a greater extent than the limits of the block of houses referred to, and to embrace an area extending east and west from Wellington-street on the west to the Law Courts on the east, and northwards of the Strand.

We do not intend now to enter into the proposed scheme, which is fraught with many difficulties of a practical nature, not the least being the principle involved in the 12th clause of the Bill, which has been termed the "betterment" clause. The principle is new; but certainly debatable, if not impracticable. The valuation and assessment would be attended with much trouble as applied to the Strand property. One thing seems clear, and that is that before the principle of "betterment" can be applied it should be demonstratively proved whether the

scheme is of Metropolitan as well as of local value, or otherwise any proposal to levy a rent-charge on property within a certain area of the property immediately benefited would be unfair.

Much may be argued for improving streets and thoroughfares from an architectural point of view. New frontages are opened for the display of architectural skill and taste. The possibilities are great, but unfortunately routine and the vexatious regulations of the Building Act interpose to prevent the carrying out of important schemes. A new street from the Law Courts through Lincoln's Inn-fields into Holborn is one of the desirable lines of new thoroughfares, and we could name a dozen other localities where architectural openings might be made with effect. The proposed amendments of the Metropolitan Building Acts have an important bearing upon the future schemes of the Metropolis. We may refer here to the proposed clause giving power to appeal against the certificate of the superintending architect as to the general line of buildings. By this amendment the vestry or district board, or any person deeming himself "aggrieved" by the certificate, may, within fourteen days after notice of such certificate, appeal to a tribunal composed of one member of the County Council, one of the Institute of British Architects, one of the Institution of Surveyors, and this tribunal is to have power to confirm or reverse or vary the architect's certificate, and the decision is to finally determine the general line of building. By this proposed provision the public may look for some guarantee that their rights will be protected in the future. Any aggrieved individual who finds that the proposed advanced line of new building will obstruct his view, or cut off the sun from his front garden, will have the means of making his complaint heard. It will not be possible for a building to project several feet before the adjoining houses, as we know has been sanctioned in instances of late. But we hope some rule, and not mere caprice, will guide the deliberations of the tribunal; without some recognised principle to act upon, we may find even a tribunal constituted as above setting up conflicting precedents, and making their decisions as uncertain as the dictates of the legal Courts. Although every case has to be determined on its own merits, there is a general law of alignment applicable to all old streets in which buildings are found of different projections. Can we say that anything like an equitable "give-and-take" line has been followed of late years? Our observations have shown that some buildings are favoured more than others, being allowed to advance beyond the "general line," that a line of new shops can be brought out several feet in advance of houses on both sides. These decisions have weakened considerably the authority who were invested with powers. One of the points upon which all will be agreed is the doubtful meaning to be attached to the provision of the existing Acts when buildings abut on more than one street. By the amended provisions, the superintending architect is empowered to decide on the lines of such abutting or corner buildings. After the passing of this Act no building or row of houses is to be erected beyond the line determined upon in such other streets in case the distance of any such general line from any highway does not exceed 50ft., or within 50ft. of any highway when the distance of such line therefrom amounts to or exceeds 50ft., notwithstanding there being gardens or vacant spaces between the buildings and highway, without consent of the Council.

With respect to height of buildings, the amended provisions specify 70ft. as the maximum height to which a building can be carried without the consent of the Council. We have before discussed the question of the height of new buildings, and

have expressed the opinion that the height would be best determined by circumstances and the width of the street. A hard and fast rule will be detrimental, as imposing, in many cases, a height that would be prejudicial to adjoining and opposite owners. More than this, the clause would create an offensive dead-level to our buildings. The necessity of considering gabled fronts is apparent. Gables ought to be tolerated, and if so the limiting line should be regulated by the height of the stories. In many streets the erection, say, of a block of flats 70ft. in height would seriously damage buildings of the ordinary height of 40ft. used as dwellings, though in wide thoroughfares such an altitude would not be felt to be an inconvenience. The width of street should be made the guiding consideration in every case. The Council, if it exercise its authority aright, ought to make its dispensing power accord with some rule of width, and not allow the maximum height to be exceeded in streets of a width under a certain limit.

The yearly growth of the Metropolis has brought into the exigencies of practical politics the desirability of affording facilities to traffic. The subway question, which is dealt with in the Subways Bill, is no new subject, but one that forces itself upon the attention of our legislators. The sooner the necessity of subways is admitted the better. Even as an economic question of street construction and maintenance, everyone must see the pressing need of doing something to save the yearly expense and inconvenience of breaking up our thoroughfares for repairs to gas and water pipes, telegraph and telephone communications. To construct a new thoroughfare without a subway for these purposes is simply short-sighted. The increasing use of overhead wires and the danger they threaten is a strong argument for some kind of legislation to place these requisite appliances under more effective control. The disfigurement they cause to buildings is another aspect it is needless to point to. In constructing a subway the question of size is one of importance. When powers are obtained, would it not be desirable to construct them of sufficient size to answer as subways for traffic as well? By-and-by the demands upon our chief thoroughfares will be so great that no police regulation will be able to cope with the requirements of vehicular and pedestrian traffic.

Our main streets at certain hours of the day are intolerably crowded and blocked by traffic of a kind that needs relief by some other channels. At all the principal corners, or where theatres and other places of amusement draw together crowds of people, we find the congested condition of traffic a great impediment, and people have to wait for an opportune moment even to cross from one side of the street to the other. There are only two kinds of relief—overhead and underground communications. Of the former, our American cousins have shown us enough rather to create our surprise than to draw our admiration. The subway is the only alternative open to us, and when, in addition to our underground railway system, we get our main thoroughfares—east and west and north and south—bored by tunnels for traffic, we shall be able to say we have utilised our roadways. In the construction of new streets the new subway communication can be as easily constructed as the foundations and basements of the houses, and, being built up and compacted together, there would be no danger of subsidence, and no compensation for damages to property. Future legislation will have to provide facilities for underground communications, and these in new thoroughfares can be extended laterally to form sub-basements for warehouses, and in this manner obviate the necessity of erecting our buildings to undesirable heights.

## THE SYMBOLISM AND ICONOGRAPHY OF EARLY AND MIDDLE-AGE CHRISTIAN ART.—IX.

By GEORGE ASHDOWN AUDSLEY, F.R.I.B.A.

(Author of "Handbook of Christian Symbolism," and several works on Architecture and Art.)

### THE NIMBI OF ALLEGORICAL PERSONAGES.

TO all the allegorical personages derived from the sacred writings and to the personifications of the theological and cardinal virtues Christian art has awarded the Nimbus, as a special sign of dignity and worthiness, or as a reflection of glory from the Godhead. It seems quite reasonable, when one realises the true significance of the attribute in art, that the personifications of such virtues as Faith, Hope, Charity, Justice, Temperance, Prudence, and Strength should be invested with the attribute in some simple treatment—that usually given to angels or the lesser saints being the most appropriate. We also find in some representations of our Lord's parables that certain of the personages there introduced are invested with the Nimbus. For instance, in the parable of the Wise and Foolish Virgins, the wise Virgins are distinguished by Nimbi. Didron states that in some instances the attribute has been given to the foolish Virgins also. An illustration of this may be found in the west porch of the cathedral of Laon, where both the wise and foolish Virgins are represented with the Nimbus. Another example exists in the north porch of the cathedral of Rheims. We should be disposed to explain this proceeding by either a want of thought or knowledge on the part of the artists. Even the Mediæval painters and sculptors were not invariably accurate in their symbolical renderings of ordinary subjects; and, accordingly, many blunders may be pointed out in their works, as some sort of excuse for the countless mistakes which have attended the modern revival of Christian art in this direction.

We may first direct attention to the interesting series of the Virtues or "Beatitudes" which adorns the arch of the left division of the north porch of the cathedral of Chartres. Five of the personifications have no names attached, or, at least, preserved, whilst all the others have inscriptions in characters of the 13th century. The names of those without inscriptions can only be guessed at by the character of the emblems sculptured on the shields they support, and by the aid given in the writings of the period. We here give the entire list, putting those in italics which are doubtful:—

PULCHRITUDO.	CONCORDIA.
LIBERTAS.	AMICICIA* (sic)
HONOR.	LONGEVITAS.
GAUDIUM.	POTESTAS or
	MAJESTAS.
VOLUPTUS.	SANITAS.
VELOCITAS.	SECURITAS.
FORTITUDO.	SAPIENTIA.

These are, with the exception of *Majestas*, which has been suggested by Didron, the fourteen "Beatitudes" given by Vincent de Beauvais in his *Speculum Universale*. All the figures appear as youthful queens, crowned, and invested with the plain circular Nimbus. The attribute is in every case sculptured in the form of a solid disc, and is placed behind the head and practically free and detached from it.

As we shall, in all probability, not have again to refer to these figures, it may be interesting to note the emblems which are sculptured upon the shields they support. The shield of the lowest figure on the left side of the arch (as the observer faces it), to which the name *Pulchritudo* has been given, bears four open roses. The shield of *Libertas* bears two royal crowns. On the shield of *Honor* are two mitres. *Gaudium* has on her shield the figure of an angel standing in

clouds and carrying a book. On the shield of *Voluptas* is an angel standing in clouds and holding a censer. *Velocitas* supports a shield charged with three arrows. The highest figure on the left, *Fortitudo*, has a lion on her shield. Descending on the right side of the arch, the next figure is *Concordia*, and on her shield are four doves. *Amicitia* has a shield charged also with four birds. On the shield of *Longevitas* is an eagle holding a sort of sceptre. *Potestas* or *Majestas* has three sceptres on her shield. Three fishes are sculptured on the shield of *Sanitas*. *Securitas* has a castle on her shield. The last figure, *Sapientia*, supports with her left hand a shield charged with a dragon, and in her right hand a small flag.

Whilst in France the circular Nimbus was universally adopted by artists in their representations of allegorical beings, the usage in Italy was by no means set and defined. Probably the most favourite form for the Nimbus of the personifications of the Virtues is the hexagonal. A good example of this form is furnished by the bas-relief of Hope, on the gate of the Baptistery of Florence, by Andrea Ugolino, 1330. An outline drawing of this bas-relief is given in Fig. 27. The Nimbus is here hexagonal with slightly hollowed sides. We have before us as we write a drawing of an ivory, of the School of Pisa, executed during the 14th century, representing Charity. She appears as a draped figure, with large wings, and invested with a hexagonal Nimbus, with straight sides. Turning now to the personification of this Virtue from the brush of the great Giotto, in the interesting church of Santa Maria dell' Arena, at Padua, we find a unique treatment of the Nimbus. The head of this figure is carefully rendered in the accompanying illustration, Fig. 28. This is the only one of the Virtues to which the great artist has given the Nimbus in any form. He evidently intended by restricting the attribute to Charity to mark her, in an unmistakable manner, as the greatest and most god-like of all the cardinal Virtues. On referring to the illustration, it will be observed that the Nimbus is a circular disc with a plain field; but that there are three frame-like emanations from the head which imparts a tri-radiated character to the Nimbus. There can be no doubt of Giotto's intention in thus treating the Nimbus of his personification of Charity. He clearly aimed at marking by an unmistakable sign the first rank of this virtue amongst all the Christian graces; and by the three flames he intended to indicate the close relationship of this great virtue to the Godhead itself. Here, again, we have a proof that the divine Nimbus is tri-radiated and not cruciform.

Several of the other allegorical beings or personifications, as rendered by the artists of the Middle Ages, are invested with the Nimbus, sometimes indicative of power and at others of holiness. The female figure, bearing the cross and chalice, personifying the Church of Christ, is correctly invested with the plain circular Nimbus; but the practice is by no means uniform. Several of the most noteworthy statues of this allegorical figure have no Nimbus. It is just worth while mentioning here that the Nimbus was never a favourite detail in connection with statues; the difficulty of rendering it in stone with any degree of propriety, or in any artistic manner, evidently discouraged its adoption. In the case of bas-reliefs, or when the figures stood in niches or shallow recesses, there was no difficulty in rendering the Nimbus, as in the case of the Virtues on the north porch of the cathedral of Chartres, as above described; accordingly we commonly find the attribute introduced by their sculptors. Sometimes the Nimbi of detached statues were formed of metal discs, Winds, Fire, Earth, Air, and Water, have and fixed behind or upon their heads.

The personifications of Day and Night, the

\* This was probably intended to be *Amicitia*.

FIG. 27.

occasionally been invested with the Nimbus, as an indication of power and not of holiness.

As we have pointedly spoken of the Nimbus as a sign of power, we cannot do better than close these notes with the following particulars from the pen of M. Didron:—

"In the West more especially, the Nimbus is commonly accepted as the attribute of holiness; a king, according to our ideas, should be adorned with a crown, whilst a Nimbus marks the saint. It is not the same, however, in the East; there the Nimbus is a sign of physical and moral strength, of civil or political power, as well as of religious authority and rank. A king is equally entitled to the Nimbus with a saint. In a Turkish manuscript, preserved in the Royal Library at Paris, there is a figure of Aurungzebe mounted on horseback and reading. The aged descendant of Timour is preceded and followed by an escort of persons on foot. The Grand Mogul is the only one represented invested with a Nimbus, circular and many-rayed. This example may serve to illustrate its application as indicative of civil power. In proof of its use in expressing religious domination, we may cite an Oriental picture, brought by General Allard from the kingdom of Lahore, representing Gourou-Sing and Baba-Nanck, founders of the Sikh religion. Baba-Nanck, its first revealer, has a radiating Nimbus; Gourou-Sing, a reformer only and a warrior, has a simple luminous circle of unradiating light as a Nimbus. Thus we discover that in the East the attribute is given to all who govern by civil power alone, by military and religious authority combined, or by purely religious authority. The Nimbus is awarded in the East to everything of a powerful nature; not to kings and saints only, but to good and evil genii, to devils and false gods; whilst, on the other hand, it is withheld from all beings destitute of power or deficient in virtue. The distinction is most easily established. All creatures supposed to be infirm, conquered, or in the act of succumbing, will be delineated without the Nimbus. It is an insignia reserved for the holy and mighty."

Speaking of the non-appearance of the Nimbus on statues, Didron remarks:—"We must guard against misconceptions; as, for instance, when statues or sculptured figures are without the Nimbus, as is the case in the grand porch of the cathedral of Amiens, it must not be too hastily concluded that the persons they represent were non-canonised. At Amiens the figures are those of very holy saints, apostles, and martyrs; and although without the Nimbus, the deficiency arises from the difficulty of sculpturing that attribute, in a satisfactory and permanent manner, around their heads, and from their being too far distant from the wall, upon

which alone the Nimbus could have been readily sculptured; and, in fact, on the arches and tympanum of the porch, where its execution was more practicable, the attribute will be found properly rendered." We have previously alluded to this matter, and are glad to be able to add the support of so great an authority as Didron.

A considerable amount of care and judgment must be exercised by the student of Christian Iconography in his examination of Mediæval works of art, for, without doubt,

FIG. 28.

the Middle Age artists were neither over careful nor invariably accurate in their representations of personages fully entitled to the Nimbus. We have seen that, through a practical difficulty, sculptors have not hesitated to represent very holy persons without art's distinguishing sign of canonisation or divinity; and that this practice was very common in connection with sculpture in stone all through the Middle Ages there can be no doubt. But the student must not on this account conclude that all the statues which adorn the porches and other salient portions of cathedrals and churches are saints, martyrs, and other holy persons. "In short," as Didron truthfully says, "neither the absence nor the presence of the Nimbus must be assumed to be an unquestionable proof of sanctity or the reverse, except, perhaps, during the period preceding and inclusive of the 14th century. After that time the important signification of the Nimbus disappears; it is given, or withheld, in a somewhat arbitrary manner. But during the 13th century, especially in certain edifices where the true signification of the

Nimbus is observed, we may affirm, as a general rule, that the Nimbus, when encircling the head of any figure, proves the person represented to be a saint. A figure of an ecclesiastic placed erect against the side of the left doorway in the south porch of the cathedral of Chartres has the Nimbus; this must, consequently, have been intended for a saint, and cannot, as some have supposed, represent the great Fulbert, bishop of Chartres, who was never canonised; whilst in all probability it may represent St. Clement, pope, for the figure wears a tiara, and not the bishop's mitre."

If the Mediæval sculptors and painters felt at liberty at any time to award the sign of holiness to uncanonised persons, it is reasonable to suppose they would do so in their statues and portraiture of the highest dignitaries of the Church; so in the case just mentioned by Didron, the tiara seems to us to be the strongest proof that the statue in question is that of a pope rather than of a bishop. In the case of figure subjects, the student is usually guided by more certain indications. For instance, if some of the figures have the Nimbus and others are without it, it is safe to consider the latter not to be saints, and all those invested with the attribute to be saints.

#### THE NIMBUS GIVEN TO FALLEN ANGELS AND POWERS OF EVIL.

Unless we accept the Nimbus to be the sign of great power, and not necessarily that of divinity or holiness, we must look upon its application to the representations of evil spirits as altogether wrong; yet in Byzantine art, in which the Nimbus has been much more freely used than in the art of the Latin Church, we find it in a few cases given to Satan. Didron gives an illustration, copied from a Bible of the 10th century, preserved in the Royal Library at Paris, in which Job is depicted seated on the ruins of his house, whilst before him stands a fallen angel, winged, and invested with a circular Nimbus. This is evidently intended for Satan. In another miniature Satan appears torturing the unfortunate Job with a red-hot goad; again this infernal being wears the Nimbus. Didron tells us that in a manuscript Apocalypse of the end of the 12th century, also in the Royal Library, are depicted "the dragon with seven heads, conquered by St. Michael; the serpent with seven heads, pursuing the woman into the desert; and the monster of the sea shaking seven heads above his frightful body. The heads all have Nimbi of yellow or green, as would be the case with the most renowned saints in Paradise. That the Apocalypse was designed and painted either by a Byzantine artist, or by one who had visited Byzantium, is sufficiently proved by the crescents emblazoned on the angelic bucklers, and the Arabic cupolas surmounting the buildings represented." In another Apocalypse, in the same library, the seven-headed beast is drawn with Nimbi on all its heads save one—the one which we are told in the text appeared "as it were wounded to death." The following pertinent remarks by Didron contain all that need now be added on this subject:—"Amongst the Orientals the Nimbus is the sign of power; a head in the agonies of death is depicted without the Nimbus. When an individual is in full vigour he is honoured with the attribute; but when enfeebled, when he is unable to resist an attack, when he is sick and death is triumphant, he is degraded and despoiled of the attribute. This seems very reasonable. In the Romanesque paintings in the church of St. Savin, near Poitiers, many instances of Byzantine influence can be traced—a notable one being the great dragon of the Apocalypse, represented at the moment of his attacking the woman who had brought forth a child destined to rule all nations: then the same monster, when he is in turn

A.D. 1855.  
Church of St. Mary and All Saints, Beaconsfield.

attacked by St. Michael and his angels. In the first picture this red dragon is full of life and power; he vomits forth from his jaws a flood of water to engulf the woman, and he is also invested with the Nimbus. He wears a yellow Nimbus, like gold, similar to that of the angel which saves the infant from the fury of the monster. In the second picture, where he is attacked by the angels, and is being thrown to the ground and vanquished, his head is despoiled of the Nimbus; and his brow no longer darts forth rays of light, because his power is ended. The rose window in the Sainte-Chapelle, at Paris, presents the same peculiarities. The beast with seven heads, bearing horns and crowns, is there repeatedly figured. Each head is invested with a Nimbus, because the beast is adored by infidels, and because his tail draws down a third part of stars of heaven. He is here all powerful and in the full display of his strength, and triumphant; but when the angel with the key of the bottomless pit chains and seals him for a thousand years—vanquished and degraded—his heads are despoiled of their Nimbi, retaining only their royal crowns.

"It is thus shown that in the East the Nimbus has been accepted as the attribute of power, either good or evil, whether it is vested in a fiend or an archangel, in guilt or virtue, in the Arch-Traitor himself, or in a god; if powerful and famous he is entitled to the Nimbus. This idea passed into the West during the intercourse with Constantinople, but it never became acknowledged in our art, and the tendency to dedicate the Nimbus to the expression of sanctity and moral virtue finally prevailed."

(To be continued.)

A Primitive Methodist chapel at Honley, near Leeds, was reopened last week, after enlargement carried out at a cost of £1,000 by local contractors, from plans by Mr. Thomas Howdill, of Leeds.

#### CHURCH OF ST. MARY AND ALL SAINTS, BEACONSFIELD, BUCKS.

By FREDERICK GEORGE LEE, D.D., F.S.A.

THE beautiful dedication of this church, set forth above, is unique in Buckinghamshire, and very uncommon elsewhere. The parish itself, containing about 1,450 acres, is bounded on the north by Chalfont St. Giles's, and Penn; on the east by the Hundred of Stoke; on the south by Burnham-common; and on the west by the Hundred of Desborough. Its population, at the end of the last century, was 1,413; now it is 1,635. The present rector is the Rev. C. H. Cholmeley, M.A., of a Lincolnshire race. He is also Prebendary of Sarum. The church is in the centre of the town, which has broad streets and picturesque houses.

The oldest portions of the material fabric of the church, as existing before its restoration, were First Pointed in character, while a few fragments of carved stone then discovered built into a part of its foundations, suffice to prove that it was probably erected about the reign of King John. It had been altered, mended, and added to from time to time—in the course of wear and tear and ordinary decay—notably in 1626, and after the Restoration of Charles II. in 1663, prior to its recent restoration a few years ago by Rector Bowles's energy. In this last work much of the old building was found to be quite beyond repair, and down to the very foundations had to be entirely renewed. The chancel was then lengthened 15ft., and the eastern portion of the nave fundamentally altered. Up to the year 1840 the church was disfigured by galleries, and had a large pulpit, with a bulky canopy, and a most capacious reading-pew, with a corresponding enclosure for the parish clerk. Private pews of varying heights and dimensions filled the building. Almost everything of interest had been cleared out by Puritan violence and destruction, though little enough is said to have remained after Elizabeth's reign. The old stained glass was broken circa 1640; the pulpit hour-glass removed in 1715.

The following notes relating to this church were made by a competent hand, Sir Stephen R. Glynne, nearly half a century ago:—

"Beaconsfield Church has a tower, with a

small spirelet upon it. The church is built of flint and stone, like the Abbey of Burnham, which gives its name to this Hundred. In the chancel are some Early English features, and in the north aisle some Decorated windows. In the south chapel is an altar tomb of freestone of good design, and there is some excellent woodwork."

There is an engraving of the church in the *Gentleman's Magazine*, Vol. LXXX., part ii. p. 105; and the brass of Thomas and Dorothy Waller, A.D. 1627, in Dr. Lipscombe's "History of Buckinghamshire," Vol. III., p. 198.

The church, as at present existing, consists of nave (with sanctus-bell turret) north and south aisles, chancel, organ-chamber, vestry on the north side of the choir, south chapel, tower at the west end, and north and south porches.

The nave, of five bays, is 22ft. 10in. wide between its Second Pointed pillars, and measures 63ft. 4in. long from east to west. Up above, on each side, there are ten lofty Second Pointed clerestory windows, quite modern, placed two and two. Including nave and aisles, the church is 52ft. 6in. wide.

In the north aisle there are three modern Third Pointed windows of two lights each of fair and effective design. Eastward of this aisle are the organ-chamber and a modern vestry, well arranged, fitted, and furnished.

In the south aisle—separated from the chancel by an old oak screen—there are four windows in the south wall, and one of a similar type at the west end, each being of two lights, and of the Second Pointed style. There is a chapel at the east end of this aisle, exactly 14ft. wide and 18ft. long. Its east window, filled with effective modern stained glass, given by the family of Sykes, is of three lights, and is in the Early Third Pointed style. Here to the north side remains an old altar-tomb (? of the Windsor family) of a very beautiful design, and in tolerable preservation. There is a simple piscina in the south wall of the sanctuary. The south window adjoining is of three lights, and in the same style. Traces of deep colour, chocolate and green, were found throughout the whole of this chapel at the general restoration of the church, together with some effective glazed tiles. A wide and lofty chancel arch contains a

Old Rectory House, Beaconsfield, 1889.

handsome modern oak screen. There are three openings on either side, with a wider entrance in the centre arch, which like all the others is cusped. Above stands a boldly-designed oak rood-cross. Below, the two central panels are pierced. The old rood-screen, of good design, has been removed to the east side of the tower arch. The chancel, 39ft. 8in. in length by 22ft. 3in. in width, is of good proportions, and has a simple and effective roof. The rises in the floor are judiciously placed, while the sanctuary has a rich pavement of singular beauty and effect. The altar stands on a well-raised platform of three steps. There is one step below the sanctuary, and two others at the chancel arch. There are three *sedilia* of stone to the south of the sanctuary, together with credence and *piscina*. All these are of new work. The south window of four lights, with heavy flowing tracery in its head, is more original than beautiful—being almost eccentric in design. To the north of the sanctuary stands, under a depressed arch, a fine old altar-tomb of Purbeck marble—probably commemorating the Scudamores—containing four quatrefoil panels on its southern side, and flat recesses in which no less than seven personal and heraldic brasses can be seen to have been originally placed. The tomb is of excellent design, of Late Perpendicular work. Over the altar, which is of good proportions, handsomely vested, and properly furnished, is a somewhat feeble reredos of stone, in the centre of which is a large crucifix, with a band of angels adoring, sculptured in one side panel, and the company of All Saints in the other. Along its crown this inscription is carved: “*For the Lamb which is in the midst of the throne shall feed them, and shall lead them unto living fountains of water. Alleluia!*” Above, well-up in the east wall, and of beautiful design and proportions, is the east window of five lights—in the Second Pointed style, filled with good stained glass at the cost of the Gould family—of which a former rector was a member. Our Lord in Glory is represented in the upper part, with the Crucifixion below. The latter was quite unnecessary, as there is a crucifix beneath the reredos, and a brass cross on the ledge behind the altar-table. Bearing in mind the notable dedication of the church, a representation of the B. V. M., seated and crowned, or with the Holy Child (as in old examples), would have been far more suitable than the repetition in question. On either side, filling the whole four lights, are representative examples of All Saints, very beautifully designed and skilfully executed. Among these are SS. Austin, Cecilia, Lawrence, Edmund (King), Helen, Katherine, Etheldreda, and Alban. The colour throughout is rich without being opaque, while the whole window is of much merit. The wall is diapered with the letters SS. and a pot of lilies in alternation. The artist here was afraid of colour, and consequently is a little feeble and weak. Below the lower sanctuary platform are rows of oaken stalls richly carved, with *subsellia* for chorister-boys. Outside the chancel arch, to the south, stands a handsome modern brass eagle

lectern, and there is a simple litany desk placed before the screen.

Around the nave, in the horizontal sills of every window, stand large vases of red rough ware of graceful design,\* made (as I learn) at a local adjacent pottery works. These are intended for flowers and evergreens at feasts, and thus adorned are more proper and effective than rough boughs of decaying leaves placed upon the window-sills.

Through the lofty tower arch, at the west end of the nave, can be seen the well-proportioned westernmost window of four cusped lights, in Late Perpendicular style. The upper and narrower lights of this window, however, are quite plain and uncusped—in this particular somewhat peculiar.

The entrance to the belfry-stage is from within the church, on the south side of the tower. Up above hangs a musical and excellent peal of eight bells, six of which are of some antiquity, but perfectly sound. Two modern bells, in memory respectively of the Right Hon. Edmund Burke and Lord Beaconsfield, recently hung, render the peal very complete. There is an old sanctus bell, under a turret at the east end of the nave. A pre-Reformation hand-bell, for use when bearing the Sacrament to sick folk, which was preserved in a chest in the church until 1851, is now said to be lost.

It is evident, from the sketch of the church before its latest restoration, that the tower and spire were never originally completed. Only a portion of the third stage was finished before the third stringcourse was reached. The corners of the tower were built in alternate squares of flints and dressed freestone. Round the top of the tower was a railing, upon the leads, and a small temporary spire with cross and vane. The proportions of the church were simple and good.

The general effect of the church—though much of it is new—is, on the whole, admirable. Of good proportions and excellent workmanship, it is at once stately, solemn, and impressive. Moreover, it is kept thoroughly clean and in good order, and so is a credit to all concerned in its restoration and preservation. In these particulars I know of no church in the diocese better worthy of a visit of inspection. It is within a walk of Uxbridge, which can be easily attained by the G.W. Railway. The main road from London to Oxford, moreover, is good.

The church was thus restored during the rectorship of the late S. J. Bowles, M.A. of Magdalen College, Oxford, the architect employed being Mr. Woodyer. Nothing appears to have been stinted nor scamped in the process, though there may have been a little more striving after originality and effect in design than I should have myself chosen.

Edmund Burke's monument—a simple marble

\* It was stated by an over-dogmatic archaeologist of the Dryadst school that these were old “acoustic pots,” similar to those discovered at Fountains Abbey; but such is a mistake, as I learn from him who gave the order for their manufacture, and placed them in the position they now occupy. See *Proceedings of the Society of Antiquaries*, second series, Vol. VI. p. 49.

tablet in the south aisle, with arms above, has the following inscription:—

Near this place  
lies interred  
all that was mortal of the  
Right Honourable EDMUND BURKE,  
who died on the 9th July, 1797,  
aged 68 years.  
In the same grave are deposited  
the remains of  
his only son, RICHARD BURKE, Esq.,  
Representative in Parliament  
for the Borough of Malton,  
who died on the 2nd August, 1794,  
aged 35.  
Of his brother, RICHARD BURKE, Esq.,  
Barrister at Law, and  
Recorder of the City of Bristol,  
who died on the 4th February, 1794.

The Manor of Beaconsfield was originally owned by the noble family of Windsor; subsequently it was bestowed on Burnham Abbey; then it came, by purchase, to the Waller race, sprung out of Kent, distinguished in war and prowess so early as the reign of Henry V. These held it for about three centuries, but disposed of it, in 1832, to Sir Gore Ouseley, Bart., from Ireland, but originally from Shropshire. Edmund Waller, the poet, lived at Hall Barn Park, to the south-west of the town—a mansion-house now belonging to Mr. Edward Levy Lawson, one of the proprietors of the *Daily Telegraph*. Waller, the poet, is buried in the churchyard, to the south of the church, where still stands a cumbersome and inelegant stone monument, with a long Latin inscription. I possess a good portrait of his son, Dr. Stephen Waller, D.C.L., of New Coll. Oxon, and of Doctors' Commons, London, painted by Sir Godfrey Kneller. He died at Bath, but was buried at Beaconsfield, where his coffin remains intact. The celebrated Edmund Burke resided at Gregories\*, adjoining Beaconsfield, now pulled down, the outbuildings only remaining.

In 1351 the advowson of the church, as the Lincoln Registers show, was in the gift of John de Huntercombe, and subsequently of his widow, Christina. Then it passed to the race of De Windsor (A.D. 1387). One of these was allowed to divide his barony, giving the Beaconsfield and Burnham portions to Walter de Windsor, his brother, whose co-heiress subsequently succeeded to the position and rank. After this, by marriage, the families of Scudamore (A.D. 1434—1548), Cheyne, Taverner, Lee, Dayrell, and Newell, respectively, presented to the rectory. In 1705 the President and Fellows of Magdalen College, Oxon, acquired the advowson, and this corporation is still the patron. John Carpenter, S.T.P., who was rector in 1430, was appointed†

\* This place, which also belonged to the Wallers, was named after a Madam Martha Gregory, wife of a well-to-do London citizen, who largely added to it. The then Earl Verney placed at Mr. Burke's disposal the sum of £20,000, with which “Gregories” was purchased. The mansion was furnished with elegance and taste.

† He was consecrated in Eton Old College Chapel, March 22, 1444, by William Ayscough (Bishop of Salisbury), Thomas Beckington (Bishop of Bath), and John Lowe (Bishop of St. Asaph).

Bishop of Worcester by decree of Pope Eugenius IV.

The old and roomy rectory house of brick and timber, standing to the south-west of the church, is no doubt as early as the reign of Edward V. It is a picturesque and convenient building, now sadly dilapidated and in utter desolation, only used for parochial meetings, &c. Some of its oaken timbers are carefully chamfered and moulded; its bricks are of a close and excellent texture and rich colour, while the plan of the building is at once convenient and good. I provide an outline sketch of it, just taken, from the south-west; some years ago it was held to be beyond repair.

The parish registers, which begin in the reign of Henry VIII., are well kept and in excellent order, thoroughly deserving of being transcribed and published. In olden times Beaconsfield was the residence of a large number of the best and most opulent families of the county. Only of late years has it lost its old character in this particular. Its situation is healthy and beautiful. The town is said to stand on table-land 35ft. higher than the cross of St. Paul's Cathedral. It is reported that the beacon fire on the Penn Hills, lit when a French invasion was expected, could be seen at Brighton.

Amongst other monuments remaining within the church—though several have been removed from their original places—are those commemorating the following families:—Jenkinson, Du Pré\*, Fuller (of Kent), Waller, Lee, Bulstrode, Elstob, Warren, Gerard (of Harrow), Sir Richard Howe, Crook, Beckwith (of Yorkshire), Bates, Staples, Baker, Stebbing, Burke, Gooch, Harris, Thorpe, Brice, Clowberry, Hyde, Read, Hillesden, Reddell, Needham, Cooke, Gosnold, Westall, Elys, Gould, Saltingstall, Burlacey, Widmore, Yates, Butler, Robinson, Gregory, Dodd, Redding, and Bowles (this latter an inscription around and within the picturesque and effective south porch).

#### NEW THEATRE AT ROANNE, ON THE LOIRE.

THIS theatre is erected upon an irregular and entirely isolated site situated to the left of the Hotel de Ville, facing the Place, and the Rue des Capucins, at Roanne, near Lyons. The architect of the building is M. E. Barberot. Every portion of the land on which the theatre stands has been cleverly utilised, and the four plans herewith printed show how the scheme is worked out. Fig. 1 gives the basement, Fig. 2 the ground plan, Fig. 3 the first floor, and Figs. 4 and 5 the second and third floors. The horse-shoe form has been adopted for the auditorium in the centre of the triangle, at the apex of which the main entrance is situated, with the grand staircase and foyer over. Some of the details of the planning are unlikely to be imitated in this country, such, for example, as the cesspits with their cleaning-out areas, below the water-closets on the other floors, shown in the basement plan at 1.1.1.1. The heating chambers are placed below the street level, that on the right, A' and A, being designed to warm the artist's rooms and apartments adjoining the stage; that on the left-hand, A" and A", is connected with the heating apparatus in the grand foyer, entrance-halls, restaurant, and offices. This work is on the Perkins' system, and was carried out by M. Ch. Gaudillot. The reference tables given with the accompanying plans, designate the chief departments of the theatre. The stage-door is at 1, the manager's room at 2, the ticket offices are at 3.3, the staircase to the amphitheatre is at 4, and Nos. 5.5.5.5 are the doorways to the building. The grand entrance opens into a square vestibule, facing the centre of which is the staircase leading to the principal tier of boxes, and the grand foyer. To the right of this is the buffet or café. The semicircular staircases in the angles of the auditorium run up from the pit level to the top floor, and could be used in connection with all of them on an emergency. The stairs are fireproof throughout. Features are made on the principal floors of large promenades at 3.3.3.3, for entracte entertain-

Wilton Park, where this family lives, another place of interest, anciently belonged to the Baldwins of Aylesbury, then to the Lees of Beaconsfield (a younger branch of the Quarrendon race), then to the Wallers, and a family named Bazil, from whom it was purchased by Mr. James du Pré, A.D. 1770, a member of a Huguenot family successful in trade. Josiah du Pré was Governor of Madras in 1770.

ments. The exterior is built in stone, and the roofs are covered with Vieille Montagne zinc. We are told that special care has been taken to insure good ventilation, and a fireproof curtain rises in front of the proscenium. The style adopted is thoroughly French in character, with a curved pediment over the main entrance, containing full-length figures representing Music and the Drama. Surmounting this feature is an immense lyre. We are indebted to the "Nouvelles Annales de la Construction" for these particulars of the building.

#### BRICKS AND BRICKMAKING MACHINERY.

By M. POWIS BALE, M.Inst.M.E., A.M.Inst.C.E.  
INTRODUCTION.

INTERESTING though the ancient history of bricks and brickmaking may be, it is not our intention to dwell on it here; but rather devote ourselves as far as may be to the consideration of the modern machinery which has been invented to save labour, to economise time, and improve, if possible, the quality of the output.

This being an age of universal and keen competition in all classes of manufacture, hand-labour has of necessity been largely superseded by mechanical means, and brickmaking has been no exception to the rule. In some cases, however, the introduction of brickmaking machinery has not proved a commercial success owing to its principle of working or construction being ill suited to the nature of the clay or mixture of clay and other materials it has had to operate on.

Clay may be broadly stated to be a mixture of the two earths alumina and silica combined with water. As to the origin of fine clay, Fownes says: "Silicates of alumina enter into the composition of a number of crystallised minerals, among which felspar occupies, by reason of its abundant occurrence, a prominent place. Granite, porphyry, trachyte, and other ancient unstratified

rocks, consist, in great part, of this minerals which, under peculiar circumstances, by no means, well understood, suffers complete decomposition, being converted into a soft, friable mass of earthy matter or clay." Gmelin says that clay is usually mixed, to a greater or less extent, with carbonate of lime, magnesia, and protoxide of iron, which cause it to effervesce with acids; it also contains manganese, finely-divided quartz, felspar, mica, organic matter, &c. all of which modify its properties and applications to a considerable extent. The presence of potash, lime, sesquioxide of lime, &c., renders it more fusible. Fire-bricks are made from a compound of silica and alumina, and the clay owes its refractory qualities to the absence of lime, magnesia, potash, and metallic oxides, which act as fluxes. Common clay or brick earth may be roughly divided into five chief classes of red, yellow, brown, blue, and black; it is found, to a greater or less extent, in many parts of the world, but differs very considerably in its chemical constituents, and, therefore, in its colour and nature, being rocky, leathery, loamy, stiff, dry, stony, rich, poor, &c.

In Great Britain some hundreds of different clays are to be found more or less suitable for making bricks; but many of these vary largely in their composition and quality, and therefore require varied treatment in their manufacture, and it is folly, therefore, to expect one kind of treatment or class of machine will act equally well on all classes of clay. It need hardly be said that in introducing machinery to secure success, great care should be exercised in its selection; in point of fact, the clay should be tried, and bricks made on several machines, and not only should the bricks be moulded, but burnt, as a clay or machine may appear to work satisfactorily, and yet a large number of wasters may be turned out. In this case it may be safely concluded that something is wrong either with the clay or its manipulation, the machine or the burning. It is never safe to trust to the casual examination of the clay for the manufacture of

FIG. 1.

bricks, tiles, &c., as we have seen on several occasions what appeared to be almost pure plastic clay, and should theoretically have made excellent bricks, burst to pieces in the drying.

The clays found in different parts of the country often require entirely different treatment; for instance, light, sandy, or loamy clays require a flux to bind them together, whilst strong clays may require an admixture of sand or loam, and others very little preparation before being made into bricks. Again, the clay may be too rich, too wet, or too stony, or, as often is the case in the

South of England and Ireland, contain small limestones, &c., which, when the brick is burnt, becomes lime, and when wetted the lime is slaked and bursts the brick. Other clays contain pebbles, metallic oxides, magnesia, pyrites, &c., and often require considerable manipulation by means of crushing, washing, &c., to render them fit to be made into bricks. In some cases, where clays contain much lime, alkalies, salts, &c., good bricks cannot be made from them under the ordinary treatment, as they warp or burst in the burning; but we hear success has been recently

achieved even with this refractory material. Again, clays which require a flux of breeze, chalk, &c., cannot be successfully moulded except under pressure, the ordinary machines using wire for cutting the bricks being quite unsuitable, unless the bricks be afterwards pressed, owing to the rough surface left on the face of the clay through the wires coming in contact with the particles of breeze, &c.

The question of clays and their constituents is largely a matter for the chemist, and a complete analysis would in many cases be of much service;

FIG. 2.

but looking at the question in a practical point of view, we cannot do better than reiterate our advice to those contemplating brickmaking—viz., to have the clay thoroughly tested and see that the process and machines adopted are exactly suited to the nature of it. By incurring a small first outlay in this connection, much loss and disappointment may often be saved. These remarks will, of course, apply equally well to the manufacture of hollow, coping, arch, feather-edged, capping, and other special bricks, tiles, pipes, &c., as it does to ordinary building bricks.

It may not be out of place here to observe that a thoroughly good brick should combine as far as possible soundness and hardness with uniformity in shape and size. It should have a good skin to render it impervious to the weather, and be capable of standing considerable compressive strain. Stock bricks, if sound and well burnt, should give out a clear, sharp ring when knocked together; some kinds of facing bricks, however, although perfectly sound, will not ring. Bricks are sometimes found streaky in section when broken, and mottled on the outside—this will often arise from insufficient pugging and preparation of the clay, a point that cannot be too much insisted on in the manufacture of first-class bricks, as layers of clay different in nature are often found in the same field, and unless these be thoroughly amalgamated, the result cannot be satisfactory.

#### BRICKMAKING PROCESSES.

Brickmaking, although subjected to many modifications rendered necessary by the nature of the clay or the kind of brick required, may be divided into two great processes (1) the plastic; (2) the semi-plastic or semi-dry. For some years much heated discussion as to the merits or demerits of these two systems has taken place; but it is not our intention on the present occasion to deal with the matter in a partisan spirit, but rather to point out briefly some of the advantages and disadvantages of each. We have seen good bricks made under both processes; but there is no doubt that many clays can be safely made into bricks under the plastic process that would be more or less failures if worked semi-dry. As a sign of the "survival of the fittest," what was formerly termed the dry process has now given place to the semi-dry or semi-plastic. The chief reason for the discontinuance of the dry process was the difficulty—although enormous pressure was used—of properly cementing together the more or less dry particles so as to form a sound and dense brick when burnt. There is no doubt, however, that very great improvements have taken place of late years, both in the method of manufacture and the machinery employed in the semi-dry or semi-plastic processes. Many clays have been dealt with semi-dry that were quite unsuited in their nature for treatment by this process; consequently when the bricks were burnt they were more or less porous,

and light cracks and flaws appeared. Consequently when the bricks were laid and subjected to atmospheric influence and wet, perhaps followed by frost, they commenced to disintegrate, and their surfaces scaled off.

Speaking broadly, I take it the clays most suitable for the semi-plastic processes are those of a bituminous or shaly, &c., nature, and which vitrify to a certain extent when fired. Even suitable clays often require careful handling, and, if very rich, to make a sound brick an admixture of fine-ground ballast, sand, or other material, in a proportion according to the nature of the clay, is necessary. These admixtures will often prevent excessive shrinking and warping of tough, stiff clays, and the ballast opens the pores of the clay to a certain extent, and permits the escape of the water contained in it. The object of the semi-plastic process is, of course, to lessen the cost of production by transferring the bricks directly from the moulding machine to the kiln without the intermediate process of drying in the air or in heated sheds, as is the case with the ordinary plastic process. Some clays will stand this treatment satisfactorily, and make first-rate bricks; but many will not. Some are of too dense a nature, and the steam formed by the water in them during the burning cannot readily evaporate; consequently, it flaws, cracks, and, in some cases, bursts the brick altogether. Again, weak and friable clays are unsuited for the semi-plastic process, but are sometimes used, and when turned out from the moulding machine possess a clean and dense appearance, but after burning they become open and weak, the particles of clay not being sufficiently bound together. Given, however, a suitable clay, and there is no doubt that good bricks may be made by the semi-plastic process, and in countries where the cost of labour is high, at a considerably less cost than with the plastic process. The clays in this country that are, however, quite suitable for semi-plastic working are comparatively limited, and the employment of this process on clays better suited to the plastic process (the result being unsatisfactory) has tended in some instances to bring the semi-plastic process into more or less disrepute. Speaking generally, the plastic process (when bricks are made and dried before passing into the kiln) may be fairly pronounced the safest in its results, and less skilful management is necessary. The matter under discussion, therefore, resolves itself into a question as to the nature and suitability of the clay to decide which process of manufacture is the best to be pursued. It may be added that, with the dry process, it is claimed that brickmaking may readily be carried on all the year round.

The duty of brickmaking machinery, especially pressure-moulding machines, is generally very severe; consequently it is necessary, to secure success, that it should be of massive construction to withstand the various strains put on it. It should be soundly made, and the various working parts

adjustable for wear as far as possible. Either from excess of competition, or other causes, this has not always been borne in mind, and the result has been in some cases machinery of far too flimsy a construction for the work it has to do. It may not be out of place here to caution users against being tempted to purchase very low-priced machinery, as a really well-designed and constructed machine cannot be sold except at a price that will give a fair return for the talent and outlay of the manufacturer. So-called "cheap" machinery is really dear at any price, as it usually means a lessened output of worse quality, combined with a largely increased bill for repairs.

#### NOTES ON PLANNING A BRICKWORKS.

The careful planning of a brickworks has much to do with its commercial success, although we are afraid that sufficient attention is not always given to this important point, the result being a considerable loss through increase of labour in handling and manipulating the materials. We are aware that all kinds and sizes of sites have to do duty as brickworks, and our remarks thereon may not in all cases apply; they must, therefore, be considered as general, and not arbitrary. In selecting a site, the chief point to be considered is the facility as to land or water carriage. Unless these are good, and the produce can be cheaply and readily conveyed to the market, the works can never be a great success, unless it be in the case of a large contract where clay can be found near at hand. Water conveyance is usually by far the most economical, and a site having this should generally be selected in preference to one having road or rail, unless the market should be within very easy carting distance. If a site is to be had with good clay on or near the surface, so much the better, as this will lessen considerably the cost of production. Having secured a site, then comes the question of laying it out to the best advantage; this must depend largely on the nature and size of the field; no arbitrary rules can, therefore, be laid down. All manufacturing works should be designed as far as may be on what may be termed the progressive system—that is, the rough material to pass in at one end of the works, through the various machines, and out at the other as manufactured articles. This principle can in many cases be applied to brickworks.

For the sake of illustration we will, in the first place, imagine a 20-acre field to make, say, 10 millions of London stocks, grizzles, and place bricks per annum. In most cases the machinery, &c., would be best placed somewhere near the centre of the field, and after the backs are made the clay brought by suitable tram lines from the far end of the field directly to the wash and chalk-mills; after being washed it would pass into the back for weathering; then, by means of elevators, to the pug-mills, which should be placed alongside, afterwards to the moulding shed, then to the stacks or drying sheds, and finally to the

kilns or clamps. After the bricks are moulded, it is important that they should be stacked so as to allow of as much air as possible to pass through them; but they should be protected from rain, sun, and strong winds. The stacks should be arranged with a slight fall, if possible, be levelled and drained, and covered with fine ashes. Many drying-sheds are now steam-heated; but about this we may have something to say elsewhere, and also of the kilns.

We illustrate herewith (Fig. 1) a neat arrangement of chain, &c., driving gear from the designs of Messrs. Bastin and Lawson, 49, Finsbury-pavement, London, E.C. It is especially designed for hand moulding pursued in the London district or where it is necessary to wash the clay. As will be seen from the plan, the windlass, driving-gear, and chalk-mill are each driven by belt direct from the engine, and the power is conveyed to the various pug-mills from the driving gear by means of chains, supported at intervals by grooved pulleys. A well is also shown from which water is raised for the wash-mill by means of a vertical barrel-pump mounted in a frame, and driven by toothed gearing from the wash-mill shaft, the clay elevator being driven by chain from the same shaft. The pug mills are shown placed in a line; but could be arranged in any other desired position, and the wash mill and elevator could be worked from the driving gear if preferred.

The selection of the engine and boiler and machinery has now to be considered, and is, without doubt, a matter of very great importance in securing successful working. With reference to the best kind of engine and boiler for the work, much will depend on (1) the quality of the feed-water, (2) the quality and cost of the fuel.

Should the feed-water be bad, a simple form of boiler readily cleaned—such as a Cornish or Lancashire—should be chosen, and these will be found especially convenient in the London fields, where ashes are used to mix with the clay, as much of the waste can thus be burnt. Where the feed-water and fuel are good a locomotive-boiler will be found economical. In brickworks the engine management is not always very skilled; and where fuel is cheap a plain high-pressure engine may often be used with advantage, the liability to break down being lessened. Where the management is good and fuel expensive, a compound condensing engine can be recommended.

The engine and boiler being secured, the question arises as to the way of transmitting the power. In the London fields, where the works are generally of a temporary character, and the plant somewhat scattered, chain-gear is usually employed, and it possesses the advantages of a comparatively low first cost and adaptability, it being capable of being readily lengthened or shortened as may be required. In the Midlands and elsewhere, where the works are more permanent and the machines not often moved, shafting is considerably used, and possesses some advantages over chain-gear; but if the machines are much scattered or at different levels, it becomes very costly, to say nothing of the large amount of power used in turning it—about 1 H.P. for every ton weight of shafting. We have recently inspected a new kind of wire-rope gearing, which has some interesting features, and possesses the advantages of lightness with strength. It consists briefly of an ordinary steel wire rope, through which are inserted at intervals a series of steel pins, fastened in a very ingenious manner, and rendering it almost impossible to pull them out. These pins gear into suitable wheels after the fashion of a pitch chain, and for long distances especially this chain should prove very serviceable. If chain-gearing be employed, the windlass should be fixed near the engine, and the chain guided and supported to the various machines, if at any distance, by a series of grooved rollers mounted on posts. For those desiring further information in this connection, the author can recommend the perusal of a very interesting paper on "Brickmaking," by H. Ward, *Proceedings Inst. Civil Engineers*, April, 1886.

If line shafting be used, steel is to be recommended in preference to iron, it being stiffer in work, and there is less strain on the bearings through the shaft springing. Steel can also be used of somewhat less diameter than wrought iron for the same duty, and, if sound, will run with less friction. The difference in first cost between steel and wrought iron is small. Line shafting

is subjected to considerable torsional and bending strains, at the same time its duty is intermittent, and has to submit to the severe, suddenly-applied loads of starting fresh machines. It should, therefore, have a fair margin of safety. A general rule for finding the diameter of a shaft suitable for transmitting a given nominal H.P. is as follows:—Multiply the horse-power by 85 for steel, or 170 for wrought iron, and divide the product by the number of revolutions per minute; the cube root of the quotient will be the diameter of the shaft in inches. If shafting is used in a very long line, it becomes at the extreme end, especially if much power be taken off, very much inclined to twist; provision must, therefore, in these cases, be made to overcome the torsion. In arranging shafting, the first length which receives the power from the prime mover should be of greater diameter than the remainder, and the bearings placed closer together. A bearing should be placed on each side of the pulley or toothed wheel receiving the power from the motor, or any pulleys transmitting large power. Brickmaking machinery, as a rule, runs at a slow speed; consequently the main line shafting must run slowly. A very convenient plan, in many cases, is to transmit the power directly from the engine to the main shaft through the medium of toothed gearing.

In the Midlands and some parts of the North of England, substantial buildings are often erected for brickworks, and their arrangement and plans differ essentially from those near London, owing to the different nature of the clay and the methods of working it. In many of these the process pursued is to hoist the clay up and pass it through several pairs of crushing rollers, and in cases where the clay is over-rich, sand or burnt ballast is added in suitable proportions. After going through the rolls the clay passes into a mixing-pan, and from thence into a pug-mill, and onwards through a wire-cutting or pressure-moulding machine, as the nature of the clay dictates. There are, of course, many modifications of these operations made in various parts of the country adapted to the nature of the clay, some of which will require a great deal of preparation, and others very little. For instance, should the clay contain large stones only, they may be generally got rid of by means of a screen fitted to the brickmaking machine; but clay containing a large number of small stones must either be washed or passed through either powerful crushing rolls or edge-runners.

Our illustration, Fig. 2, represents some of the various gears used in the London brickfields with a new form of elevator, designed by Mr. W. Eddington, London, to take the place of the ordinary vertical chain or belt elevator. Fig. 2 represents a chain-gear windlass mounted on a wrought-iron pug-mill, and arranged with spur-gearing on the slow motion. In practice, however, it will usually be found much more convenient to fix the windlass separately on a foundation of its own. B shows an intermediate motion fixed on a pug-mill. C represents a chain-driven wash-mill made with wrought-iron sides and frames for ready removal. D represents a wheel elevator, made of angle-iron or steel, and it is claimed that this arrangement is an improvement over the ordinary form of elevators, the wearing parts being quite out of the dirt and slurry, the wear and tear is very little, and that the driving-power required is much less than for pumps. E represents a clay-truck, worked by the winding-gear G. A saving of time will be effected if the truck is arranged to dump automatically. The best class of clay trucks are fitted with steel axles running in chilled-iron boxes.

#### YORK MUNICIPAL BUILDINGS.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

THIS work is in course of erection, from the designs of Mr. E. G. Mawbey, A.M.I.C.E., now borough surveyor of Leicester. The plans were prepared by him when he was city engineer at York. The site is at the north side of the Guildhall, which it adjoins, and the frontage faces the Ouse. The style of architecture is Perpendicular, its features harmonising with the old building. Tadcaster stone is being used in the construction of the frontage and the north elevation, and green Westmoreland slates for the roof. The principal entrance is from the Guildhall, in the north-west corner, near the temporary offices of the City Survey and staff. The lower

story, or basement, is situated 15ft. above the summer level of the river. A large stone balcony fronts the river, a corridor and thence a flight of steps leading to the landing-stage at the end of Common Hall-lane, being a far more desirable approach than the latter passage, which is at present used. The basement corridors are lined with a dado of glazed bricks of suitable tints, and the floors laid with Venetian marble mosaic. On the same floor are the lavatories and other accessories. The drainage is carried out on the most modern scientific principles. The plans further show rooms for samples, stores, and plans, strong rooms for the town clerk and city accountant, and a heating-chamber. The whole of the building is to be heated by hot-water apparatus, and in conjunction with this system thorough ventilation is arranged for. In most of the rooms there will also be fireplaces for occasional supplementary heating purposes and to meet emergencies. On the ground floor are the offices for the town clerk and the city surveyor, and a large committee room. On the first or principal floor above the ground floor is the council chamber, 50ft. in length, 33ft. in width, and 28ft. in height, with a frontage to the river. It is lighted by four stone-mullioned, tracery windows, about 13ft. high and 7ft. wide. A fine oak-timbered Gothic ceiling, with moulded arch, and longitudinal and transverse ribs, and richly-decorated panels, and bosses at the intersections, will be a noticeable feature, as also the walls, which will carry a handsome moulded and panelled oak dado about 6ft. 6in. in height, and a richly-panelled and carved cornice. A moulded and carved oak chimneypiece, having a suitable inscription bearing upon the inauguration of the building, will likewise add interest to the chamber. The floor will be of polished oak. The accommodation of the Lord Mayor, aldermen, and councillors is to be on an entirely different plan to the present. His lordship's seat will be at one end of the room, and to his right and left sit the aldermen, immediately in front being the town clerk's seat, and contiguous to the latter the seats for the other principal officials. The councillors will also occupy separate stalls, which are to be arranged in four segments of a circle, the form somewhat resembling that of a horse-shoe. Each member will have a desk in front of his seat and accommodation for writing. In the centre of the room will be a table for exhibiting plans, &c. Reporters are accommodated to the right of the Lord Mayor. At the opposite end of the room, slightly raised above the ordinary level, will be a space set apart for the public, who can be accommodated to the number of 70 or 80. Adjoining the council-chamber are an ante-room and retiring rooms for the Lord Mayor and members of the Corporation. Lavatory accommodation is also furnished. On the same floor are to be the city accountant's offices. The caretaker's quarters are on the floor immediately above. The floors throughout the building are of fireproof construction; iron joists and Portland cement concrete being used. The staircases will be of stone, the balusters having rouge royal marble copings. The main entrance from the Guildhall opens into a large vestibule, from which the grand staircase ascends. There is also a supplementary working staircase at the north end of the building. The cost of the new building, exclusive of the site, will be from £11,000 to £12,000. The contractors for the work are Messrs. Lowe and Sons, Burton-on-Trent, and Mr. English is the clerk of works.

There has been unveiled in the nave of Moor Criche Church, in Hampshire, a stained-glass window of three lights. In the centre is the figure of the Virgin and the Infant Saviour, round the heads of whom are shown seven doves, typifying the seven gifts of the Holy Spirit. On the right-hand side is seen St. Peter, and on the left St. Paul. All the details are designed in the style of the 15th century. The figures stand within niches, surmounted by canopies. It is erected as a memorial of the late Lady Alington by Lord Alington, and has been executed by English artists, under the direction of the honorary architect, the Rev. Ernest Geldart, of Little Braxted Rectory, Essex.

The Edinburgh town council have had under consideration the underground railway proposed to be carried through that city and in Leith and Newhaven by the Caledonian Railway Company, at a cost of £750,000, under a Bill to be submitted to Parliament next session. The corporation have appointed Sir John Fowler and Mr. Benjamin Baker as their consulting engineers.

## WAYSIDE NOTES.

HAVING duly rested on our oars, or, to use a more appropriate metaphor, on our T-squares, for the holiday season, we should all be in a fit condition to enter upon the pilgrimage along what course 1890 may take in the river of years. Let us hope that its earliest days may unfold to each of us a bright vista, with health and happiness, and a plethora of "jobs" ahead, of which a smaller percentage than of yore may prove to be the shadowy phantoms we all too well know! And, judging by the appearance of things, and the exercise of reason, the opening of the New Year is one of some, perhaps of very considerable, promise. For the past two years or so, I believe I am warranted in saying that trade in general has been prospering, and if 1889, by no means so bad as it might have been, has not satisfied all, we may expect to feel beneficent results, should things in general continue to improve. Although we know that, after a long period of depression, it takes some time for the rising wave of prosperity to greatly affect the building interests, a third year should certainly find them brisker and more lively than for some time past.

John Bull considers his architect last of all. He does not care to launch out into building schemes until he sees the ground perfectly safe, until, that is to say, he has put by a goodly pile. His jeweller and picture-dealer, even, participate in his good fortune before the gentleman that supplies his plans. J. B., conservative as he is to the backbone, whatsoever he may term his political views, hesitates long to exchange old lamps for new. The new house, the rebuilding of business premises, and manifold other long-contemplated schemes involving extensive building operations, that he may have been well able to afford a year or more ago, he delays to the last.

In the competitive branch of business the year opens briskly. There must be an unusually large number of men engaged in preparing competition plans, for at the present moment competitions are as plentiful as architects in and around Bedford-row, or as engineers in Great George-street. I do not remember so many coming at once for some time past, and do not hesitate to take them as straws upon the surface of water, showing an improvement in the volume of business. There may not be anything particularly attractive about the last arrivals—the advertisements from the Leeds Corporation and from the Lion Brewery, at West Hartlepool; but they help to keep young architects employed, and improve chances all round.

The engineers have already lost one of the jobs included in the year's list of Parliamentary Bills, the scheme for the construction of the City and North London Subway Railway (which was to have joined the South London Subway, now approaching completion), with a station in the City-road and passing en route King William-street and Moorgate-street, having completely fallen through. Perhaps it is as well, for any public money that might have been devoted to the work, for the usefulness of the proposed line is by no means so evident, as is that of the line under the Thames to South London. This latter undertaking should prove a success. It will not now, I believe, be a very great while before it is quite completed. The stations are being constructed, and, although the patching up and adapting of Deane's old premises in Fish-street-hill does nothing to improve the architectural outlook of the neighbourhood, there is arising opposite St. George's Church in the Borough, a structure of brick and stone with a domical iron roof that should contrast well with its surroundings.

Now that light subway railways seem rather in fashion, I would suggest that one would be eminently useful between the Northern suburbs of London and the Charing Cross district. There must be a considerable volume of traffic between these points, and a number of persons daily going backwards and forwards, amply sufficient to render a small railway a paying concern. There must also be a very large number of persons whose business is in the west-central district who would live in the north-western suburbs if better means of intercommunication were at hand. If there are many others having my own horror of daily 'bus riding, this number must be large indeed. It appears to me that a

light railway, starting from, and connected by subways with, the South-Eastern and District Stations at Charing Cross, and running along under Duncannon-street, Charing Cross-road, Tottenham Court-road, and Hampstead-road, and serving Kentish Town, Camden Town, and Hampstead and Highgate, would, if properly carried out, and—if this be possible!—escaping the blood-sucking of company-mongers, prove not only a financial success, but a boon to Londoners.

The Channel Tunnel again! Sir Edward Watkin is not to be pacified with the "Watkin" tower, and thinks charitably of his rival, the proposed Channel Bridge. His perseverance merits ultimate victory. At the extraordinary general meeting following the ordinary general meeting of the Channel Tunnel Company, held in the board room of the South-Eastern Railway Company last Tuesday, it was proposed to introduce into Parliament in the ensuing season, "A Bill to authorise the maintenance and continuance of the experimental work for a tunnel beneath the Straits of Dover"; and on the 16th inst. a meeting is to be held to confirm the proposal. Of a choice between the tunnel and bridge, I see that Lord Wolseley favours the latter. This, of, course, is on military grounds. From an engineering point view, there can be no two opinions, excepting that one cannot expect the designers of the bridge to do aught but believe in their own scheme. I am glad to see that many having right to speak on the question, condemn the bridge as little short of an absurdity. The tunnel one can imagine constructed with safety; but the engineer who could put up the bridge might well be considered an extraordinarily clever man.

It might be put up—the question is, how long would it stand? In theory, the construction of the bridge presents no difficulties, neither can one deny the accuracy of theory in M. Jules Verne's romances. When we come to practice, however, things wear a different aspect. How such a structure as M. Hersent and M. Schneider propose is to stand against the effects of winter gales remains to be shown. We know how, in the past, those doubting the possibility of this and that have had to eat their words; but at the present day there is a marked tendency to believe the capability of human ingenuity to accomplish everything and anything without questioning its possibility. There are numbers of persons who, should someone come forward with a scheme for a tunnel or bridge between England and the American Continent, would have difficulty in persuading themselves that the thing was impracticable.

The folly of open street ventilators to sewers I have often urged. If we are to have them closed we should all surely share in the beneficial results. It seems to me manifestly futile to stop up the ventilators in one place and so give the nearest gratings a double share of duty, to the detriment of the atmosphere immediately surrounding them. From a notice issued by the secretary of the Stock Exchange, regarding the sanitary condition of this building, I learn that certain openings into the sewers near it have, by pressure brought to bear upon the Commissioners of Sewers, been stopped up, and others are shortly to be closed. But what does this mean? Simply that the foul air issuing from neighbouring open ventilators is rendered infinitely more filthy. I am glad, for the sake of the members of the Stock Exchange, that this effort to improve the atmosphere surrounding their building has been successful, while sympathising with those who may be losers by the arrangement. I could not desire to see the gratings uncovered again, but a general loud complaint on the part of the public against the barbarous system of ventilating sewers under their very noses. Nobody, either private or public, has a moral right to inflict the stenches of an open, or, what is worse, a closed, sewer upon a single citizen.

The system of city sewerage that I have before now advocated is one of air-tight pipes and sewers, wherefrom the foul gases are drawn by means of suction, created either by fan-wheels or by draughts to furnaces, the latter plan seeming at first sight the simplest, because all the filth is passed through a purgatory fire. This

burning of the foul air I consider indispensable to the completeness of the scheme, so that whether exhausted from the sewers by fan-wheels, or by draughts to chimney-stacks, it would have to pass through a refining fire. Sooner or later, some reformation in the method of ventilating the London sewerage system, must be seriously taken in hand. We cannot long continue suffering under the present absurd system, a practice which I have said is barbarous, and one that exhibits not one iota of true advance upon the open sewerage of the Middle Ages. Indeed, it is easy to argue that it is a retrogression, since in an open drain there is not the generation of foul gases that occurs in the pent-up sewer.

The commencement of the New Year is a good time to reflect upon the course that architecture is pursuing. We are still plodding along on a highway, the foundation of which is Classic. Gothic architecture is at a discount—as low-priced as it has been since the palmy days of the great Revival. It is almost wholly relegated to the care of ecclesiastical architects, and of a few men on whom the trammels and traditions of the School of Neo-Gothicists have still a firm hold. In the judgment of those competent to give an opinion, the most pleasing exponents of architecture as a progressive art at the waning of the 19th century, are those who combine originality of composition with a studied regard for refinement in detail, subordinating what is called "style" to the attainment of these qualities. So, those who affect style and neglect composition, and adapt hackneyed detail, are the least deserving of respect. The former are the true architects, and the latter the machine-like imitators, and, compiling automata, of a type altogether behind the age.

Mere originality, without intrinsic beauty, however, is now happily held to be of no merit. Let us be thankful for the light that has been shed in this direction, and hope that 1890 may witness a steady continuance along the same road as we have been travelling upon of late years. Having taken to heart the lessons of the Revivals with their slavish copyism, and remembering the no less important teachings of the originality-at-any-price gentlemen, let us avoid the two extreme principles that have only led their advocates to ultimate artistic ruin and destruction; and, working in the light of their failures, we may then combine to assist that true progress in modern British architecture which, despite the carpings of critics, has assuredly been made since the days when ape-like imitation was thought to be at the root of manly art, and since the no less evil times when a fetish-worship of so-called originality was spread over the length and breadth of the land. GOTH.

## WROUGHT IRONWORK BY MESSRS. STRODE AND CO.

THE examples we show in our illustration are of recent issue from the well-known forges of Messrs. Strode and Co., of 48, Osnaburgh-street, Regent's-park, and as characteristic types of this interesting handicraft are well worth attention. The sign shown on the left hand of sheet was a commission from Mr. Heath for his new premises in Oxford-street, where it has now been fixed for some time. The small hall lantern, the bracket support of which is suggestive of a cornucopia, is a tasteful rendering of the best period of the Cinque-Cento, and is an exquisite piece of workmanship; this has been exhibited at the late Arts and Crafts, but had previously taken a prize at the Blacksmiths' Exhibition.

The staircase balustrading was once executed for a town mansion; the treatment of the grotesque newel post is somewhat novel, being a combination of forged and *repoussé* work, thus producing the necessary bulk without excessive weight.

The remaining works have all been fixed in different parts of London, the lamp standard and railing (both good examples of the Georgian type we are familiar with) figuring at branches of the London and South-Western Bank.

A new organ, built by Forster and Andrews, Hull, for St. Mary's Episcopal Church, Hamilton, was dedicated on Friday. The instrument has been erected in an organ-chamber at the north side of the chancel, the front pipes projecting beyond the arch. A pitch pine case has been provided, and the front pipes are richly decorated.

## OUR LITHOGRAPHIC ILLUSTRATIONS.

## CONTEMPORARY BRITISH ARCHITECTS.

We commence this week a series of photographic portraits of living British architects, which cannot fail to be of interest to our readers. We invite other architects to further our scheme by sending us their cabinet photographs, so that gradually, and from time to time, a complete collection of portraits of contemporary architects may be secured. We take this opportunity of thanking those who have already responded to our wishes in this matter, or have assured us of their early help. The selection will include the presidents of the London and Provincial Architectural Societies, the architectural members of the Royal Academy, the Royal Scottish Academy, the Royal Hibernian Academy, &c., and also others distinguished for their works either artistic, constructional, or literary in connection with the art of architecture.

Our first group to-day begins with Mr. Alfred Waterhouse, R.A., the President of the Royal Institute of British Architects. His first great work was the Manchester Assize Courts, followed by the Gaol at Salford; the Cambridge Union Society's new house; the new University Club, St. James-street, S.W.; Church of St. John, Brooklands, near Manchester; Hutton Hall, Stanstead Abbots; Bank, Lombard-street, E.C.; Lime-street New Hotel, Liverpool; Balliol College, Oxford; Caius College, Cambridge; Manchester Town Hall; the Natural History Museum, and the City and Guilds of London Institute also at Kensington; Eaton Hall, Chester; the Prudential Assurance Company's Offices, Holborn, W.C., and in Dale-street, Liverpool; St. Paul's School, Kensington; St. Elizabeth's Church, Parish Hall, and Schools, Reddish, near Manchester; the Law Insurance Office in Lincoln's Inn-fields; Heythrop Hall, Oxon; Turner Memorial Home of Rest, Liverpool; Owens College, Manchester; Yorkshire College at Leeds; National Liberal Club, Whitehall; Girton College, Cambridge; Liverpool University College; Infirmary at Liverpool; the Weigh-house Chapel, Mayfair; and the Hotel Métropole, now building at Brighton. Mr. Waterhouse is a distinguished water-colour artist, and has frequently exhibited in the water-colour gallery at the Royal Academy, as, for instance, in 1888, when he was represented by a study of the grand ruins of Girgenti, and a view of the Aventine from the Ponte Rotto. He served on the jury for art at the Paris Exhibition last year. As professional referee in many of the leading competitions of the day, he has taken a foremost place, and at the present time is engaged in this way with the Sheffield Municipal Buildings Competition, the

designs for which were received last month. He was the professional representative for England on the Milan Cathedral competition a year or two since. Besides the works we have enumerated, Mr. Waterhouse has designed a large number of minor importance, such as Reading Town Hall, as originally built, and the premises at the corner of Old Bond-street. His own house at Tatten-don, near Newbury, where he is lord of the manor, is an important mansion. He is a Royal Gold Medallist of the R.I.B.A. The portrait given herewith is from a photograph by Messrs. Brown, Barnes, and Bell, of Baker-street, W.

Mr. Richard Norman Shaw, R.A., whose name is so familiar in connection with the development of domestic architecture, is now busy building his greatest work in London on the site of the National Opera House (which was abandoned years ago) for the head offices of the Metropolitan Police. The building has a return front facing the Embankment close to the Houses of Parliament and St. Stephen's Club. The principal elevation is placed towards the new street which runs between Parliament-street and the Embankment. Mr. Shaw's first building in London which attracted particular attention was New Zealand Chambers in Leadenhall-street. He also built Lowther Lodge, South Kensington, the great pile of mansions overlooking the Albert Hall; Bedford Park, Chiswick (church, stores, club, and some houses); the houses of Mr. Luke Fildes, R.A., and Mr. Marcus Stone, R.A., at Holland Park, Kensington. The late Mr. E. W. Cooke's house at Tunbridge Wells was one of his earliest residences, and about the time of its erection Mr. Norman Shaw was associated in practice with the late Mr. W. Eden Nesfield. Before this partnership Mr. Shaw worked in the office of the late Mr. George Edmund Street, R.A. Craig Side, Northumberland, and Adcote, Shropshire, are among this architect's largest houses. He also designed another called "Pierpoint," Surrey; the "Wispers," Midhurst; a house at Sunninghill; Mr. F. Goodall's house at Harrow Weald; Swan House, Chelsea; some others in Cadogan-square; the Clock House, with more of the same type, on Chelsea Embankment; the new galleries and refreshment-rooms at Burlington House, for the Royal Academy of Arts; Dawpool, Cheshire, is one of his great mansions; a house and studio for Mr. G. H. Boughton, A.R.A., at Campden Hill; Mr. H. P. Heseltine's house in Queen's Gate, Kensington; another one, also in red brick, in the same road, and Mr. Bazeley White's cement-dressed dwelling adjoining the Imperial Institute, likewise in Queen's Gate. At Hampstead Mr. Shaw built houses for the late Mr. Frank Holl, R.A., and Mr. Edwin Long, R.A., as well as his own house in Ellerdale-road, and Miss Kate Greenaway's house in the same neighbourhood. St. Margaret's, Ikley, Yorks, and St. Michael's, Bournemouth, are two of his churches, and he has built another lately for the Mission at Latimer-road, as well as the charming English Church at Lyons, one of Mr. Shaw's most effective earlier buildings. Other foreign churches have been erected from his designs in India and elsewhere. "Greenham Lodge," Newbury, is one of his latest mansions; "Walhampton," for Mr. Heseltine, in Hampshire, and "Merrist Wood," Surrey, were built some few years ago. The large block of assurance offices at the bottom of St. James-street, S.W., was designed by him for the Alliance British and Foreign Office, a Bank in Bishopsgate-street, E.C., and also the Children's Hospital at Coatham. Mr. Norman Shaw published his book of "Sketches from the Continent" in 1858, and in 1878 he published, in conjunction with Mr. Maurice B. Adams, a folio of designs for Cottages and other Domestic Buildings. We cannot attempt to mention more of Mr. Shaw's many works. His portrait is from a photograph by Mr. Bassano, of Bond-street, W.

Following the arrangement of the portraits on our sheet we come to Mr. Ernest George, F.R.I.B.A., whose first important work when in partnership with the late Mr. Vaughan, was Sir Henry Peek's splendid house at Rousdon, Devon, where a church, and whole series of lodges and cottages were carried out. In London Mr. George has of late years designed many important street buildings in conjunction with Mr. Peto, in South Audley-street, Wigmore-street, Cheapside, Mount-street, and at the corner of Berkeley-square; the Albemarle Hotel, Piccadilly; at Collingham-gardens, and Harrington-gardens, Kensington, are several of his houses; and there are two more in Cadogan-square, S.W.

At 6, Grosvenor-place, is some more of his work, and at Streatham is a coffee tavern, a memorial church, and smaller residences. "Woolpits," Surrey, was built for Sir Henry Doulton; at Ascot is another mansion. The Knoll, Barton; Little Croft, New Forest; Earl of Onslow's lodge and cottages, Clandon; cottages, coffee house, "Barrow Point," and "Eastcote Lodge," all at Pinner; Beechwood, Kent; Helier's Almshouses at Guildford; house at Harpenden, and another at Streatham-common; "Bagshot," "Rosehill," Henley; "Champion Hill"; the Redesdale Hall, at Moreton-in-the-Marsh; "Dunley Hill," Dorking; "Buchan Hill," Sussex; Batsford; Stoodleigh Court, Devon; church at Tarasp, Switzerland; coffee tavern and hostelry, Newark-on-Trent; South Hill, St. Laurence-on-Sea; and Convalescent Home at Leigh, Kent. Mr. Ernest George has published several books, among these being "German and Swiss Sketches," "Sketches on the Mosel," "Etchings in Belgium," "Sketches on the Loire," and "Etchings of Old London." He is a prolific water-colour artist, and constantly exhibits at the various galleries, and he is a member of the Royal Society of Water Colour Painters. Mr. Ernest George's portrait is from a photo. by Mr. Bassano, of Bond-street.

Mr. John Loughborough Pearson, R.A., the architect of Truro Cathedral, has chiefly devoted himself to church building, and has built too numerous a list of works to mention all here. He was a pupil of Ignatius Bonomi, of Durham. Among his earlier designs were Treberfydd House, S. Wales; Quar Wood House, Gloucestershire; Holy Trinity Church, Westminster; and others at Dalton Holme, near Beverley; North Ferry, Scarborough, Hilston, and Appleton-le-Moors; St. Mary Stow, Lincolnshire; Weybridge, Surrey; Sutton Veny, Wilts; Dalesford, Worcestershire; Titsey, Surrey; Landscorn, Devon; Ayott St. Peter's, Herts; Rhydymwyn, Flint; Freeland, Oxfordshire; St. Peter's, Vauxhall; Chiswick parish church; St. Augustine's, Kilburn; church at Horsforth, near Leeds; St. Michael's, Croydon; St. John the Evangelist, Red Lion-square; St. Agnes' Church, Toxteth Park, Liverpool; St. Stephen's, Bournemouth; Wentworth Church, Yorkshire; and many others of less note, as well as schools and other buildings, such as St. Peter's Convalescent Home at Woking. The additions to Westminster Hall, the restoration of Westminster Abbey, and the rebuilding of the central tower of Peterborough Cathedral are among Mr. Pearson's most important undertakings. Rochester Cathedral is also being repaired by him. Westwood House, Sydenham, illustrates the way in which a Gothic architect can work in the Renaissance style. The new buildings and library for the University at Cambridge are among his latest erections. Mr. Pearson is a Fellow of the R.I.B.A. and a Royal Gold Medallist. He is also a Fellow of the Society of Antiquaries. His portrait is from a photograph by Mr. Lewis, Isle of Man.

Mr. F. C. Penrose, M.A., the surveyor to St. Paul's Cathedral, is a distinguished archaeologist and Greek scholar, well known for his great work on the "Investigation of the Principles of Athenian Architecture," first published by the Dilettanti Society, in 1851. He was the first Director of the English School of Archaeology at Athens, founded a few years ago. He prepared a scheme for the decoration of St. Paul's Cathedral. He opened up the foundations of old St. Paul's, to be seen on the south side of the present church, and he arranged the open space in front of the cathedral, as well as the churchyard. He built the choir schools for the Dean and Chapter, and has added to St. John's College buildings at Cambridge. Many churches have been restored by Mr. Penrose, and he has added to others, as St. Stephen's, Walbrook, as well as to several country houses, amongst which we may name the Marquis of Bristol's great mansion on the hill in Ickworth Park, Suffolk, where he decorated the living-rooms. Mr. Penrose is a rapid draughtsman in water-colours. He is a Past Vice-President of the R.I.B.A., and Gold Medallist. The portrait given is by the Stereoscopic Company.

Prof. George Aitchison, A.R.A., B.A., Professor of Architecture at the Royal Academy, is better known for his decorative designs. He is architect to the London and St. Katharine Dock Co., to the Founders' Company, and to the parish of All Hallows, Barking, and is a district surveyor. He was a pupil of his father. He built Sir Frederic Leighton's house at Holland Park,

and carried out some residences commenced in South Audley-street by the late Mr. Frederick Cockerell. He erected some schools at Trent, near Dorset, and Farley, near Salisbury, and some warehouses in the city of London. He has contributed several papers to the R.I.B.A., and he is a vice-president of that body at the present time. He designed a house for Lord Richard Grosvenor at Stalbridge Park, Dorset, and has decorated houses at Brighton; 52, Prince's-gate, Kensington; some rooms in Kensington Palace; 1, Grosvenor-crescent, and 29, Chesham-place. He designed the hall (13, St. Swithin's-lane, E.C.) for the Founders' Company, and built some large offices in Pall Mall for the Royal Exchange Assurance Company. This building has a front also in St. James's-square. In Chesterfield-gardens Mr. Aitchison has done some costly decorative work for Lord Ilchester, who also employed him at Melbury, Dorset. Our portrait is from a photograph by Messrs. Fradelle and Young, of Regent-street.

Sir Arthur William Blomfield, M.A., A.R.A., F.S.A., past vice-president of the Institute and a former President of the Architectural Association, has been busily engaged in erecting buildings all over the country for very many years. Among his more notable works lately are the additions to Eton College, and the Sion College new building on the Thames Embankment, Blackfriars. He has just been elected architect to the Church House to be built in Dean's Yard, Westminster, and his great church of cathedral proportions at Portsea has recently been opened. The Law Courts, in the Strand, were completed under his direction conjointly with Mr. Arthur Edmund Street, after the death of Mr. Street. Sir Arthur has erected more than we can possibly even mention here, and among these works we may name St. Saviour's Church for the Deaf and Dumb in Oxford-street, as well as a vicarage adjoining; Church in Bell-street, Edgware-road; St. James' Church, Paddington, remodelled; St. John the Baptist Church, Great Marlborough-street; St. John's, Wilton-road, S.W., and the rearrangement of St. Peter's, Eaton-square; also the Chapel Royal at Brighton, and Quebec Chapel, Mayfair; a church in the Marylebone-road; New Church, Glanadda, Bangor; St. John's, Wenbridge, Yorkshire; Private Chapel, Tynsfeld, near Bristol; SS. Peter and Paul, Upton-on-Severn, Worcester; Church of the Holy Trinity, Privett, Hants; St. James's Church, Southampton; St. Barnabas' Church, Oxford; St. George's Church and the Albany Chapel at Cannes; Clock Tower, Liverpool; New Schools, Repton, Burton-on-Trent; Denton Manor, Grantham; the Whitgift Schools at Croydon; Choir Schools, Chester, and restoration work in the Cathedral there, and the new Branch Bank of England in Fleet-street, which is this architect's greatest work in London. The photograph reproduced to-day is by Messrs. Maull and Fox, of Piccadilly.

Mr. William Emerson, F.R.I.B.A., the author of the chosen design for Liverpool Cathedral, was originally with Messrs. Habershon and Pite, but he became a pupil of the late William Burges, A.R.A., and afterwards practised in India, where he erected several important buildings, such as Messrs. Treacher's premises in Bombay. He also built the Takhtsingji Hospital, Bhavnagar; the Muir College and Allahabad University, All Saints' Cathedral, Cannington, near Allahabad, and Girgaum Church, near Bombay. Mr. Emerson was one of the competitors for the Berlin Houses of Parliament and the Victor Emmanuel Monument at Rome. He built himself a house at Little Sutton, Chiswick, where several houses have been erected from his designs. St. Mary's Church, facing Rock-gardens, Brighton, is a notable building, and among other works from his hand in this country are some offices and warehouses in the City. The portrait given to-day is reproduced from a photograph by Messrs. W. and A. H. Fry, of Brighton.

Taking our second sheet of portraits, we come to Mr. William Young, who has just completed the Glasgow Municipal Buildings, which great work he won in competition. He built Lord Cadogan's mansion, Chelsea House, Knightsbridge; Viscount Bury's mansion in Cadogan-square; Lowther-gardens, Exhibition-road; a row of mansions in Cadogan-square, Chelsea; Holmewood House, Hants; Easton Lodge; Gosforth House, cottile, and staircase; Broadwater Down, Tunbridge Wells; Oxhey Grange, Hants; Earl Stanhope's house, Chevening Hall,

Kent; his own house at Putney, and several similar houses in different places. He is the author of "Picturesque Architectural Studies," and "Town and Country Mansions," published ten years ago. He is the editor of Spon's "Architect's Pocket Book," issued yearly. The photograph given herewith is by Mr. Deneulain, Strand, W.C.

Mr. Aston Webb, F.R.I.B.A., the recently-elected hon. secretary of the Institute, is now building, in conjunction with Mr. Ingress Bell, as joint architects, the New Law Courts at Birmingham, a work of the first importance. These gentlemen competed together for the new Admiralty Offices and for the Imperial Institute, and we illustrated their designs at the time. Mr. Aston Webb's most important work in London is the restoration of the church of St. Bartholomew the Great, W. Smithfield, and he has since erected some new schools for the parish. Other works of his in the City are some warehouses, Great Eastern-street, and offices in Austin Friars. In the county of Worcestershire he has practised largely. In Worcester he restored one of the city churches, built some large Sunday-schools, and a series of memorial almshouses. Claines Church and Alfrick Church, Worcester, he renovated, and built Wick Vicarage, Pershore; Penycal Church, N. Wales; Burford Church, Tenbury; Rhos Parsonage, S. Wales; "The Briary," Cowes; "New Holme," Bromley, Kent; "Brackenwood," Higher Babington, Cheshire; house, Ewhurst, Surrey, and 20, Queen-street, Mayfair, are other instances of his design. Mr. Webb was Pugin student in 1873, and he is a Past President of the Architectural Association. His portrait, given to-day, was taken by Mr. H. S. Mendelssohn, S. Kensington.

Mr. T. E. Collcutt, F.R.I.B.A., is the architect of the Imperial Institute now building at South Kensington, which he won in competition, and he also erected Wakefield Municipal Buildings some few years ago. After serving the late Mr. George Edmund Street, and working in the town surveyor's office at Brighton for a short time, Mr. Collcutt commenced practice in the City with Mr. Woodzell, and erected some marble works at Pimlico and furniture warehouses in the Tottenham Court-road. After this Mr. Collcutt erected Messrs. Collinson and Lock's premises in Fleet-street and Bride-street, E.C.; a series of houses at Mill Hill, where he also built a library for the late Sergeant Cox. Other works of his are a row of residences for the late Mr. Jennings in Nightingale-lane, S.W.; houses, Hayes-common; hunting lodge, Winchfield, Hants; house, Sheen-common; new premises, Oxford-street, for Messrs. Phillips, and a furniture shop adjoining; bungalow at Winchfield; house, East Sheen; lodges, Easton Park; a house at Paris, built originally for the Paris Exhibition in 1878. He obtained the second premium for the town hall at Barrow-in-Furness, which we illustrated at the time; he erected himself a large house in Bloomsbury-square, and previously one at Ravenscourt Park, W.; he has designed the fittings for several line steamers, and is well known for his furniture designs. The great theatre now building in Cambridge-circus is from his hand, and the Savoy Hotel was fitted up inside to some extent under Mr. Collcutt's supervision. A new hotel at St. Helier's, Jersey, is about to be erected from his designs. He was the winner of the Grand Prize for Architecture at the Paris Exhibition this year, the only other Englishman so distinguished being Mr. Norman Shaw, R.A. His portrait is by Mr. Barraud, of Oxford-street.

Colonel R. W. Edis, F.S.A., commands the Artists London Volunteers, and he built their headquarters. He is a member of the London County Council. His works are too numerous to name; but he erected the Constitutional Club in Northumberland-avenue, and is about to build the Junior Constitutional Club in Piccadilly, where he carried out the Badminton Club a few years ago. He designed the new ball-room at Sandringham for the Prince of Wales; the Inner Temple Library; Victoria Mansions, Victoria-street, S.W.; Westwoodhay House; Rudolf Memorial Church; an art gallery in Bond-street, and some premises higher up in the same thoroughfare, and a shop at the corner of Brook-street; the offices of the Legal and General Life Assurance Society, Fleet-street; Byrkley Lodge, Staffordshire; house at Brighton; one at Petersfield; another at Eastbourne; schools for the London School Board, Battersea; hotel,

Boscombe Spa, Bournemouth; Memorial Fountain, Huntingdon; the Arts Club interior, Hanover-square; St. Paul's Wharf warehouses, E.C.; warehouse, Budge-row, E.C.; houses at Bexley Heath; "Bents Brook," Holmwood, for Sir J. E. Boehm, R.A.; Ringwood, Hants; stables, &c., Great Marlow; Bishop's Palace, Buckden, Hants; row of houses, Constitution Hill, and several residences in various parts of the country. He went to America some years ago to lay out a city there, and he is a past president of the Architectural Association. His book on "The Decoration and Furniture of Town Houses," with illustrations by Mr. Maurice B. Adams, was issued a few years since, and a series of sketches from France appeared in the BUILDING NEWS from his hand about 20 years ago. His portrait to-day is by the Stereoscopic Company.

The photographs of Messrs. Leeming and Leeming conclude our selection of portraits to-day. These architects distinguished themselves by winning the competition for the new Admiralty and War Offices, Whitehall, Mr. Ewan Christian being the referee. They also won the Edinburgh Municipal Buildings competition a year or two ago. The contract for the foundations of the Admiralty Offices, as finally determined upon, has just been made, and the work will be now proceeded with. Messrs. Leeming were first in practice at Halifax, where they built some large mills, chapels, and schools. They are among the competitors for the Lisbon Post-Office buildings, not yet decided. Their portraits are by Mr. Deneulain, of the Strand.

#### REID'S NEW HOTEL, MADEIRA.

ALTHOUGH Madeira, like many other places, has its bad days, and occasionally even its bad seasons, it may be fairly said of the place that it enjoys perpetual summer. Placed as it is on the highway to the Cape, it has become not only a place of refuge for those who are compelled to avoid the severities of an English winter, but it has also become to some extent a place of holiday resort. The hotel, of which we give a view, is in course of building to meet the wants of the increased number of visitors, none of the existing hotels having been built with a view to modern requirements. In laying out the plans of the new building, the peculiarities of the site and advantages of view and aspect have, as far as possible, been considered. The building stands on a promontory of volcanic rocks rising some 150ft. above the Atlantic. The plan shows that the approach is from the back; but so quick is the slope of the rock towards the east, that beneath what must be termed the ground-floor level there are three stories. The rooms on the principal floors are all provided with large balconies, so that the enjoyment of the open air may be obtained by those who may be too unwell to leave the hotel. The building is laid out in two blocks, the south and east. These are joined on the ground-floor level by the large drawing-room and entrance hall, common to the two blocks, which are, however, in other respects isolated. This arrangement is made so that when guests are few they may not have large empty passages to traverse, and should illness break out in one block, it can be isolated from the other. It has been essential, for the sake of economy, to study the methods of construction, and to use the materials common in the island. The walls are built of rough volcanic stone, plastered. The window dressings, and a few features of cut stone as doorways, are of the local "Cantaria." Such architectural effect as the building may have is entirely gained by blocking together of masses, detail being quite out of the question. From the covered balcony of the drawing-room, a balcony which in such a climate is really a part of the room, is obtained a most superb view, extending across the bay of Funchal to the rocky group of the Desertas hanging on the horizon. The building was designed by Messrs. Somers Clarke and J. T. Micklethwaite, 15, Dean's-yard, Westminster. The sanitary arrangements are under the care of the Banner Sanitation Company, which has already entirely remodelled (and with the most satisfactory results) the four existing hotels in Madeira belonging to Mr. Reid. Commodious billiard and recreation rooms are placed in the garden at a level somewhat below that of the hotel and near the lawn-tennis ground, whilst in other parts of the garden are small detached residences for those who prefer greater privacy than is afforded by the hotel itself.

"THE ADORATION OF THE KINGS," CERTOSA, PAVIA.

THIS group of sculpture, representing the Virgin and Child worshipped by the Heavenly Host and Wise Men, forms the principal subject of the large mural decoration on the east wall of the chancel on the Gospel side of the apse in the choir of this great church at Pavia. The commencement of the apse itself is just seen to the right of our illustration. The "Last Supper" is represented in the long panel below, the whole being richly inclosed in marble framings and panellings. On the other side of the sacrum there is a similar piece of work, with the piscina for the high altar below, in the place of the "Last Supper," with a representation of God the Father above the receding cornice, which forms the quasi-niche for the central group, as in the sculpture herewith represented. A pediment surmounts the whole, and above, on the wall, is a full length figure of the Saviour enclosed by angels. Corresponding to this in the south side is a statue of the Virgin.

BEDROOM AND KITCHEN, CASTELLO DI VINCIGLIATA, NEAR FLORENCE.

THIS most interesting castle presents an imposing aspect with its crowning towers, encircling walls, and battlements, standing as it does on the summit of a hill some two and a half miles from Florence. A splendid view can be had from its ramparts, and a journey out to see the place should not fail to be made by the excursionist. Tickets to view may be obtained at No. 14, Piazza Pitti, from the proprietor, Mr. Temple Leader. This gentleman, who is an Englishman, bought the property in 1855, and has since restored it, the architect being Sig. Giuseppe Fancelli. Considerable skill and ability have been shown in the work of reconstruction, and the rooms contain a vast collection of works of art and antique furniture, some of which may be seen by the two drawings accompanying these notes. The history of the Castle of Vincigliata commences soon after A.D. 1000. Its successive owners were the Visdomini, the Usimbardi, the Accordi da Figline, the Buonaccorsi, the Albizzi, and the Alessandri. These last, who had the property in their possession for several centuries, sold the castle in a greatly ruined condition in 1827. As a Mediaeval revival, the building certainly possesses an interest peculiarly its own, and the remains of the ancient structure were carefully retained in the rebuilding, which Fancelli carried out. The interior accords with the outside; but to the English architect probably the most interesting portions of the castle will be found inside, where the furniture, lamps, weapons, armour, clocks, and ornaments are arranged *in situ*. The walls of the "Sala del Consiglio" are enriched with frescoes above a panelled dado, and the ceiling is vaulted like the Armoury and Salotto da Colazione, where heraldic bearings enrich the spandrels. Our view of the brick-groined kitchen is taken looking out of "La Dispensa," which is level with it, and contains some fine chairs and a cabinet of rich detail. The sink and the kitchen fireplace, with the old spit apparatus, are seen in our drawing. We may give others at an early date.

THE TE DEUM.

THIS cartoon, designed by Mr. Christopher W. Whall, the well-known decorative artist, of Stonebridge, Dorking, is executed in water-colour and pastel, and forms one of a series of six panels illustrative of the Te Deum for a piece of mural decoration. The subject for this picture is the text—

"Thou art the King of Glory, O Christ.  
Thou art the Everlasting Son of the Father."

The original was exhibited last month in the New Gallery at the Arts and Crafts Exhibition.

CASTLE OF FREDERICKSBORG, DENMARK.

FERGUSON says, in his only too brief notice of this grand and really fine building, that it may be regarded "as another warning not to look for true art among people of such purely Teutonic blood as our cousins the Danes." This opinion must, however, be taken, of course, as the judgment of a purist, written with the idea of furthering a taste for Classical integrity of design; but nowadays eclecticism governs popular taste in architecture as in everything else, and fashion has turned its favour upon *baroque* forms, while some, more restless still after novelty, are directing their attention to uncompromising Rococo detail in their compositions.

Dutch crudities have found their imitators, and so-termed "Queen Anne" has been done to death, like the Gothic mania which went before, or the Japanese craze which a few years ago affected in a way the fancy of some cultivated decorators. The truth, of course, remains that in all these types, as well as those of the Renaissance of Germany, Belgium, and Denmark, there exists much that well befits modern uses and the scope of everyday building, and even in their more elaborate and grandiose specimens, as in the simpler examples, the architect, with judgment, necessarily finds style, method, and design, both worthy of study and imitation. The Renaissance of Denmark is comparatively little known in this country, and good illustrations of the principal buildings erected by "our cousins the Danes," are not to be found in any English architectural books that we are acquainted with. Rough sketches now and again have been given, or small unintelligible wood blocks figure in popular hand-books. For study, of course, detail is necessary, and this is what Herr Fred. Skjold Neckelmann has made a feature of in his valuable folio of photographic plates just issued by that indefatigable publisher, Herr von Ernst Wasmuth, of Berlin, under the title of "Denkmaeler der Renaissance in Daenemark."\* We cannot do better, therefore, than to accompany our drawing which we print to-day, from the Castle of Fredericksborg, with a brief notice of this most useful book to which we direct the attention of our readers. Comparisons have been made between the Jacobean art represented by Heriot's Hospital, or the Castles of Stirling and Edinburgh, and the Danish Castles of Elsinore and Fredericksborg. Fergusson indicates that he could almost believe they were the work of the same architect. Probably this was, to some extent, the case, and other buildings could be easily enumerated to endorse this idea. Christian IV. erected both castles, as well as the Exchange at Copenhagen, and he was the brother of Anne of Denmark, the Queen of our James I., who owed so much to the Scotch goldsmith, "jingling Georgie," the founder of the great Edinburgh Hospital. (For drawings of Heriot's Hospital see BUILDING NEWS, March 1, 1889.) Fredericksborg Castle stands on three islands, and its towers rise with an air of grandeur and graceful grouping, while its weather-stained walls declare its antiquity. Inside, the building has been done up, and many of the decorations and tapestries are modern. The view which we give is taken from the great quadrangle on the second island, and standing on what is called the Terrace, looking over the bridge which leads through the portal, in the middle of the screen, into the inner quad, where the big tower called the Kirchenturm rises in the centre of the left-hand wing, as seen in our drawing. The smaller octagonal tower known as the Koenigsturm, shown to the right of this picture, is one of the two turrets flanking the arcade in two stories which fronts the main building, in which are situated the principal apartments. The walls of the castle are of red brick laid in courses of headers and stretchers, with stone dressings everywhere. The roofs are covered with lead. The chapel, which occupies two stories in the left-hand wing adjoining the great tower, is a richly-groined apartment running north and south, with arcades on either side, and a gallery, triforium fashion, all round. In the aisles are pews, one in each bay of the arcade, with tall, carved fronts brought forward flush with the arches. There are two organs, one being placed in the gallery over the altar; but the principal instrument is at the north end, and it is particularly handsome. The altar has a triptych, beautifully sculptured, and the pulpit, boldly projecting from the second bay of the arcade, is an equally florid piece of work; in fact, every part of the chapel is ornamented. The font stands close to the altar. The Gothic-like windows are filled with very poor glass. This chapel is celebrated as the crowning-place of the kings of Denmark. The Knights' Hall, or what we should probably call a ball-room, is a somewhat overdone apartment, having every inch elaborated with ornament, from the marble floor to the coffered ceiling; but the plain general massing of the wall piers between the windows insures dignity and gives a solidity

which sobers down the over-elaboration greatly. The new tapestry is very good and interesting. The groined hall or "Rose," as it is called, has some wonderful plaster-work, the stags and other beasts reminding one of the ornamental work at Hardwick Hall, Derbyshire. The armour and rich dado woodwork give great character to this part of the castle. The Chamber of Waldemar II., is quite modernised, and has a hooded chimney-piece of marble and stone, calling to memory the hideous similar one which disfigures the great library at Blickling Hall, Norfolk, and put up at great cost some years ago by a decorative designer, who ought to have known better. The surrounding buildings and gateways to the castle are most interesting, and so are the gardens skirting the lake beyond. These at one time were most famous, and the park is a beautiful place. Most of the rooms in the building contain some feature worth seeing. Among the other specimens of the Renaissance of Denmark, brought together by Herr Fred. Skjold Neckelmann, in his book, to which we have referred, are the Exchange at Copenhagen, the Castle at Kronborg, the Rosenborg Castle, which is rich in old Jacobean furniture, and its marble rooms; the "Dyvekes Haus," at Copenhagen, and besides some other samples of Domestic work from the same place, he gives a whole series of the Holmenskirke, which furnishes several examples of curious detail. The church itself is plain; but the high altar, the great pulpit, and the monuments on the walls give it richness of effect, and enhance its importance. The seating too is worth noting. The Heiligengeistkirche is another specimen of similar character. The letterpress descriptions to the work are from the pen of Professor F. Meldahl, director of the Kunst Academy of Copenhagen. The printing and paper are all that could be desired.

"LADY MACBETH WALKING IN HER SLEEP" (ROYAL ACADEMY SILVER MEDAL CARTOON).

THIS prize design for a draped figure received the Royal Academy Silver Medal a week or two since, and is the work of Mr. Paul Raphael Montford, of Battersea. It represents Macbeth's guilty consort as depicted in scene 1, Act 5 of the Tragedy. Our remarks upon this and the other competitor's works at Burlington House for 1889, will be found in the BUILDING NEWS for Dec. 13th last.

YORK MUNICIPAL BUILDINGS.

For description, see page 10.

LUSTRE AND ANGLO-PERSIAN TILES.

THESE excellent Tiles have been designed by Mr. L. A. Shuffrey, and are made by Mr. J. C. Edwards, of Ruabon. The lustre tiles rival the finest examples of Mediaeval, Spanish, and Italian ware, and are unsurpassed as regards the gorgeous effect of their opalescent colour. The "Anglo-Persian" tiles are simply reproductions of the exquisitely beautiful ancient Persian tiles, which they rival in their design and softness of colouring. Our illustration opposite very inadequately reproduces the work itself, but enough is shown to show to what a height of perfection Mr. J. C. Edwards has attained in the manufacture of these really admirable decorative tiles.

The question of erecting a new and larger Fine Art School for Wakefield than the present building in Bell-street has for several years past engaged the attention of the council of the institution. Plans for a new structure, prepared by Mr. William Watson, architect, of Wakefield, have been approved by the council, and also by the Science and Art Department. The tenders have just been let for the various works, and the building, which is to be commenced at once, will entail an expenditure of £5,000. Sir E. Green, M.P., will lay the corner-stone at an early date. All the work will be executed by Wakefield tradesmen.

A meeting of the vestry ratepayers and parishioners of St. Mary-le-Strand was held at the Vestry-house on Dec. 27th, at which the "betterment" clause of the Strand Improvement Bill was universally condemned, and a resolution was passed asking the Strand District Board of Works to use its best efforts to oppose and prevent the passing of the Bill.

Dante Gabriel Rossetti's "Beata Beatrix" has been presented to the National Gallery by Lady Mount-Temple.

## ARCHITECTS' REGISTRATION IN AUSTRALIA.

LAST month a large party of members of the Royal Victorian Institute of Architects visited Sydney on the invitation of the sister institute of New South Wales. At the dinner, which terminated the very successful proceedings, and which was held at Roberts's Hotel on the 8th Nov., Mr. Lloyd Tayler, F.R.I.B.A., President of the Victorian Institute, in proposing the toast of the New South Wales Institute, remarked that on the Victorian side they were engaged in a very great work affecting the architects' interest and the position they would occupy in public estimation. They had nearly concluded the incorporation of their institute. A Bill for the Registration of Architects would shortly be introduced into their Parliament. (Applause.) A few years ago the medical community in Victoria were in the same position as the architects were now. Any man who chose could simply put up a brass plate and call himself an architect, and those who were qualified felt that they were unworthily associated with them. They were therefore going in for a Bill which would be so comprehensive that no one with the slightest claims to be called an architect would be excluded from it. They were obliged to consent to this, in view of the great good they anticipated in the future. They were most anxious to follow the British Society of Architects as far as possible. Their Registration Bill was now drafted and waiting settlement. The rules applicable to an old country were not always applicable to a new one, and, as regarded by-laws, there was some little difficulty. They should insist that if a competent man did the work he must charge his 5 per cent. That was a necessity in a new country.

## COLD AND DAMP HOUSES.

A LARGE proportion of the colds and ailments of the respiratory organs suffered during this season of the year are attributable to the want of proper measures being taken by builders in laying foundations, and in executing the basements of our houses. Hundreds of the houses let in the suburban districts of London are built upon clay and marshy ground, often of "made earth" and rubbish. The present by-laws as to foundations and building sites have been in operation only a few years; but previous to that time houses were built upon decaying matter deposited by dust contractors, the foundations of walls were laid on the damp soil without concrete or proper courses to prevent the rising of damp in them, and damp earth was allowed to extend above the basement floor level. By the legislation of recent years, these matters have been more looked after by the district surveyor. We may point now to a few of the causes which contribute to cold and uncomfortable houses. First and foremost is the imperfect arrest of dampness from the soil. The only way of securing a healthful house is to cut it off as much as possible from the soil on which it stands. Ideally, one may imagine a house standing on stilts or piers, having a free current of air below, and a stair up to the floor; but this would be unattainable under existing arrangements. The next best thing is to obtain a well-ventilated cellar, or, what is almost as good, a sufficient air space between the ground and the floor, this space being well ventilated by bricks, and the ground covered with asphalt or concrete. Neither of these essentials is found. There is an air space below the floor; but it is generally a rough and unlevelled surface of rubbish, with the air bricks so scantily introduced, and they often clogged up by earth or dirt, that the air is in a state of stagnation, and the emanations from the soil are sucked up into the house by the warmth and fires. Another danger is added if a disused cesspool or a drain is beneath the house, and who knows how many of our houses are built over these receptacles of a past civilisation? The many houses and tenements built almost level with the ground are particularly open to suspicion. A fast-decaying floor or a mildewed appearance of dampness, or musty smell, under oilcloth or linoleum in the hall or passage will reveal the evil. On examination it is found, on taking the rotten boards up, that the joists are close to or rest on the ground, that the bond timber is rotten, or no damp-proof course inserted. Hundreds of small houses are found yearly in this condition of incipient decay, which

often begins under the passage floor, near the staircase or back door. The only remedy is to excavate the soil, underpin the walls, and lay a damp course over soil, replacing the timber on sleeper walls of proper construction. The want of ventilation is usually found to be the cause.

Houses having half-basements or parlours below the ground floor are very common in the Metropolis; but these as living rooms are highly objectionable, with the exception of those which have not been excavated, and are built up from a lower natural level in the rear, in which case the lower story becomes the ground-floor story of the house behind. Then it becomes necessary to form a good area or retaining wall in front to give light to the front room, or, if there is no front room, to well line the wall forming the back of the room in the rear with some bituminous compound. It is better, perhaps, to make it thick and hollow, ventilating the space. And speaking of half-basements leads us to dwell on one or two points connected with dry areas. Walls built against earth ought to have an area formed along it of its whole height. On the return side of semi-detached houses the side wall must be built often without any area, and in this case the space next the wall for a foot or more should be filled in with broken stone, and a drain be placed at bottom just below the level of footing. An asphalt coat on the outer face of wall returning in the joint at the floor level should invariably be put. A more efficient protection would be an area covered over next the outer wall, called a "French intercepting drain," or a concealed area. Sometimes an impervious tile-facing has been placed against the outer face of a wall so built; but of all these plans the open ventilated area is the best. We have here referred chiefly to foundation and basement measures; but the dry wall and the well-protected roof are other necessities of warm and healthful dwelling-houses.

## BOOKS RECEIVED.

*The Ancient Laws of Wales*, by the late HUBERT LEWIS, B.A., of the Middle Temple, &c. Edited by J. E. LLOYD, M.A., Lecturer in History and Welsh at the University College of Wales (London: Elliot Stock, Paternoster-row). is an interesting work attempting to "trace in the local institutions, of Mediæval and Modern England vestiges of a state of society similar to that described in the Welsh Laws." The author discusses first the Welsh evidence, and next Old English institutions, both show clearly a common British and Aryan origin. Mr. Lewis describes in detail the social system of Wales, how it was based on the freeholding heads of households who belonged to a joint family or *Tref*, belonging in its turn to a kindred or *cenedl*, having a chief (*pencaeredl*) and elders. The kindreds were organised into a larger *Tref* called *cantref*, and this was divided into *cwmneds* or neighbourhoods for convenience. The lord of the *cantref* held a legal court, over which he presided. In these courts the freeholders acted as judges, decided disputes under sanction of their administrative head. The *cantref* with its court was a perfect organisation, and remained for a long period under certain modifications, sometimes combining under one prince. These free brotherhoods contained various orders. Those who were strangers (*alltuds*), and settled within the *cantref*, became in time subordinate members of the community, with lands, rights, and privileges, but were still under burdens, and had no share in the privileges of the brotherhood. The Free Brethren, how they held their lands, the rules of inheritance, rights of succession, and the lord's rights over his *alltuds* and *aillts* (the latter being a term to denote those who forfeited their privileges) are discussed. The author points to the parallel between these elements of the Welsh social system and those of England. Thus the settlement and emancipation of *alltuds* explain how a manor in time included freeholders. The English rules as to strangers show a similar procedure. The private lord having assumed his right to the territory over the lower tenants, he gave out wastes to free men, and the dues and services were rendered to him. The manor became by usurpation a "small hundred" of which the tenant held. The author shows the similarity between the Welsh and Anglo-Saxon laws. Anyone receiving a stranger must not keep him more than three nights without presenting him to the court, when, unless he departed, he was assigned to

villanage. The Saxon "folkmete" took the place of the royal court. The enforced bondage of strangers is common. Again the evidence points to a remarkable similarity between the "hundred" of England and the *cantref* of Wales, and the number 100 is a territorial unit found in many other countries. So with the Welsh and English manors. Some interesting facts and much learning are given bearing on these and other questions, into which we cannot possibly enter. The chapters on the English manorial courts, showing that the court corresponded to the Welsh *Taeogtref*; the feudal succession, showing how Alodial rules became a part of the feudal system; commons and local nomenclature are questions possessing much interest both to those engaged in the study of the law and to antiquaries. Mr. Lewis and his learned editor, Mr. Lloyd, have shown at least that a very remarkable analogy exists between Welsh and English institutions, which undoubtedly supports a common British origin. Considerable research was called for, the examination of numerous documents, amongst them the Laws of Hywel, and the differences in the three codes of that law, was a labour calling for prolonged study and learning.

—*Building Construction*, by CHARLES F. MITCHELL, lecturer on Construction, Science and Art Department, &c., second edition (London: B. T. Batsford, 52, High Holborn). This new and revised edition of a work we reviewed on its first appearance shows how great has been the demand for a book of this description. The author, Mr. C. F. Mitchell, lecturer at the Polytechnic Institute, Regent-street, has in this elementary course given students a useful summary of the different branches of construction, each trade being revised by specialists. The engravings are accurate and exceedingly well executed. For students preparing for the May examinations of the Science and Art Department no better text-book can be given.—*The Anatomy of Pattern*, by LEWIS F. DAY (London: B. T. Batsford), is a second edition of a very useful manual, to which we have previously drawn attention. The title best explains the intention of the author, whose mode of pattern dissection, applied to all kinds of patterns, cannot fail to be of value and suggestion to all students of art, and especially the decorative artist and designer.—*Revived Guild Action* (second edition), by GEORGE SHAW (London: Simpkin and Marshall; Kent and Co., Limited), is an account of the steps taken by the Court of the Plumbers' Company to revive the action of the company in the training of the plumbing craft. To Mr. Shaw was committed the task of preparing a pamphlet on the subject, and no one could have performed the work with more efficiency and ability than the Master of the Company. The preface contains an interesting history of the movement and the resolutions which led to the establishment of examinations for plumbers and their registration. The suggestions to the Warden and Court of Plumbers' Company are important. Mr. Shaw herein shows the benefits conferred on crafts and the public alike by the old organisations or Trade Guilds, which provided for excellence of craftsmanship, and the mischievous results of the modern organisations, which have tended to separate the workman from the employer and to disorganise the classes; but he also points to a revival, in part, of the old corporate system in several trade establishments who have a corporate body, with special rules and privileges for the employes, such as sharing in the increased profits of the business. The trades unions make no provision for efficiency of their numbers, and herein lies the weakness of the modern system. Mr. Shaw next shows the necessity of the revived action in the case of plumbers, and describes the extent and importance of the plumber's work as a sanitary requirement. The appendix is full of information, and Mr. Shaw's little pamphlet will be read with interest.

## LA GROSSE HORLOGE, ROUEN.

THIS picturesque archway, erected 1527, connects the adjoining tower with the old Hotel de Ville. The sketch is by Mr. Arthur H. Hind, A.R.I.B.A.

The St. James's Theatre is being redecorated and re-upholstered by Campbell, Smith, and Co., 75, Newman-street, Oxford-street, London, W.

LA GROSSE HORLOGE, ROUEN.—*Sketched by A. H. HIND, Leicester.*

# ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

**NORTHERN ARCHITECTURAL ASSOCIATION.**—The second ordinary meeting of this association was held on Monday night in the Old Castle, Newcastle, Mr. Joseph Oswald presiding. Mr. J. H. Morton, F.R.I.B.A., read a paper bearing on the paper of Mr. W. H. Dunn, read at last meeting, on "Architects as Scientists." In Mr. Dunn's paper the merits of engineering had been contrasted with the skill of architecture to the disparagement of the latter. He (Mr. Morton) thought that the time had gone by for them as architects to pretend to know all things. Architects had to try to know too much as it was. When, therefore, any man had work to design of any real importance, which was out of the ordinary run of his practice, he need not be ashamed to say that he had called in the assistance of an engineer. He would even venture to suggest that the architect who in these advancing days did not get an engineer to assist him in his design made a mistake and endangered the interests of his client. One the other hand, why should the engineering constructor not occasionally call in the aid of the architectural designer? Why should all our building operations of the so-called engineering order—viaducts, bridges, great roofs of railway stations, &c.—be left barren and unfruitful of grace, because the designers of them professing nothing of the artistic spirit themselves, assumed that it had no connection with their work? Certainly the most enthusiastic could not call the Forth Bridge a "thing of beauty and a joy for ever." However great a triumph of engineering skill it might be, he ventured to assert that it was one of the ugliest structures in Great Britain. Let them contrast that structure with the Tower Bridge across the Thames, designed by the late Sir Horace Jones, who was associated with Mr. Wolfe Barry in carrying out the work. Certainly the structure was on a much smaller scale, and under vastly different conditions; but it was acknowledged by architects and engineers alike to be a most picturesque one. With regard to the decay of stone in buildings, a firm in Leeds had produced a material for glazing stone so that a building might be enabled to be kept clean by means of the rain. The stone was glazed before being fixed, at so low a temperature as not to injure the stone. He thought that the education of students was worthy of the consideration of that association, as, if the profession was to hold a high place in the estimation of the public, the standard of excellence should be a high one. He very much feared that as a profession there was an absence of culture among many of its members, and that it was open to the most illiterate persons to adopt the name of architect and to practise the art. Let them bar the entrance to their profession, as had been done in others, by the test of skill and attainments, and he believed good would result, as by raising the tone of the individual admittance to their profession would be an honour and a distinction, better men, both socially and intellectually, would be tempted to join them, and inferior ones would be deferred. A discussion followed, in which Mr. Plummer, Mr. Moscrop, Mr. R. F. W. Rich (secretary), Mr. Dunn, and the President joined.

## COMPETITIONS.

**FREE LIBRARY, NOTTING-HILL.**—In a recent limited competition for the proposed new free library at Ladbroke-grove, Notting-hill, W., plans were invited from eight architects nominated by the commissioners. At the final meeting held to consider the plans, the design bearing motto "Tree of Knowledge" was selected, the authors of which were found to be Mr. T. Phillips Figgis, A.R.I.B.A., and Mr. H. Wilson.

St. Allen parish church, Cornwall, has just had a three-light painted glass memorial window erected in it by Messrs. A. L. Moore and Co., Southampton-row, London. In the left-hand light the subject illustrated is "Christ Restoring Sight to the Blind"; in the centre it is "Christ Blessing Little Children"; and in the right hand "Christ's Charge to His Disciples." Above and below there are canopies and bases in the Decorated style, corresponding with the shape of the window.

Mr. Littler, C.B., Q.C., Chairman of the Middlesex County Council, will present the Government prizes and certificates to the successful students of the Hornsey School of Art, Crouch-hill, on Wednesday evening next.

# Building Intelligence.

**FLIXTON, SUFFOLK.**—There has just been completed a memorial chapel to the Adair family at the west end of the north aisle of the parish church at Flixton. The chapel has been built at a cost of £900, borne by Sir Hugh Edward Adair, Bart., on an octagonal plan in the style of transition from the Early English to the Decorated period. Externally the walls are of rubble flint, with Ancaster stone dressings and angle buttresses, with hipped roof of Staffordshire tiles, surmounted by a gilded cross. The roof bosses are carved with the quarterings of the Adair family. The windows are plain glass, with slightly-tinted borders. The chapel measures 12ft. 9in. by 10ft. 7in., and is 14ft. in height. The floor is of mosaic in red, white, and dark grey Devonshire marble. In the centre, on an alabaster pedestal, is a life-size statue in white marble of the Lady Theodosia Adair (the wife of the late Sir Shafte Adair, afterwards Lord Waveney) in a kneeling posture, the work of the late J. Bell, sculptor. Lady Adair died 1871, aged 61 years, and was buried in the family vault in the chancel. The architect was Mr. Mr. F. B. Wade, F.R.I.B.A., Victoria-street, London. The work has been carried out by the contractor, Mr. John Thompson, of Peterborough, under the superintendence of Mr. R. M. Searle, clerk of the works.

# Engineering Notes.

**THE INVERNESS AND AVIEMORE RAILWAY.**—At a meeting of the directors of the Highland Railway at Inverness on Friday, tenders for the construction of the works of the Carr Bridge section of the new direct line from Aviemore to Inverness were considered, and it was unanimously resolved to accept the offer of Messrs. John Ross and Son, contractors, Fearn, Ross-shire. The length of the section is 6 miles 917 yards, and there are in course of the distance 19 bridges and culverts for roads and streams. The total contract price is £27,733, but the Railway Company provide the permanent way and fencing. Messrs. Ross and Son have only recently made the line from Keith to Buckie for the same company. The contract stipulates for the line being open to the public by the 1st of May, 1891. Arrangements are now being made for letting the contract for the second section of the line, extending from Carr Bridge to the River Findhorn.

The Jubilee town-hall at Linlithgow, built at a cost of £3,500, was formally opened by Lord Rosebery recently.

The tower and spire of Holy Trinity Church, Scarborough, have now been completed, and the Archbishop of York preached a special sermon in connection with the undertaking on Sunday.

Mr. Chester, one of the contractors for the Thirlmere Aqueduct, has brought an action against the Manchester Corporation to restrain them from acting on the notice given on Christmas Eve to seize and take possession of the works for which he has contracted, and the plant and materials thereon; and on Saturday afternoon last his counsel, Mr. Ashton Cross, obtained from Mr. Justice Denman, sitting as vacation judge, an order for an injunction restraining the corporation from taking possession of the works and plant over the first motion day of next sittings, the 11th inst.

A meeting of the Worcestershire Jubilee Memorial sub-committee was held at the Shire Hall, Worcester, on Tuesday, for the purpose of having an interview with Mr. Brock, A.R.A., and inspecting a model of the Worcestershire jubilee memorial. The model was unanimously approved, and Mr. Brock will now proceed with the completion of the statue of her Majesty in accordance therewith, and it will be placed in front of the Shire Hall in May next. The cost of this statue will be £1,700. It will be of white Carrara marble. The figure of the Queen will be wrought out of one block, weighing 17 tons, but which when it leaves the sculptor's hands will weigh nine tons. The statue will be something more than life-size, and will stand upon a plinth, which will rest upon a massive pedestal also of white marble. Beneath this is a sub-base and a granite foundation rising in three steps. The highest point of the statue will be 23ft. above the ground level. The Queen stands crowned, and wearing a robe of State; in her right hand she holds the sceptre, and in her left she supports the orb.

## TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to J. FASSMORE EDWARDS.

## TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.). To India (via Brindisi), £1 10s. 4d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

## ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

## SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING for TWENTY-FOUR WORDS, and Sixpence for every eight words after. All Situation Advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page advertisements and alterations in serial advertisements must reach the office by Tuesday Morning to secure insertion.

## NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XLII, XLVI, XLIX, L, LL, LIII, and LVI, may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—Major R.—P. and F.—R. G. T.—E. G. T.—C. C.—W. O. and Son—E. H. B.—J. R. C.—W. M. M.—J. D. and Son—R. L.—W. T. and Son.

## "BUILDING NEWS" DESIGNING CLUB.

DRAWINGS RECEIVED.—"Mac," "A in a circle," "Wal-laby," "The Red Rover," "First Attempt," "A. G. in a circle," "West Anglian," "I Try," "Dr. Jekyll," "Sarchedon," "Niger," "Bunya," "North Star," "Dot" (if you do not put your correct name and address on the back of every drawing you must not expect to have them returned), "Streona," "Syak," "Renaissance," "K. W. T.," "Argus," "Glaucus," "Menehaus," "Nox," "Paul Jones," "Multum in Parvo," "Lord G.," "Coverae," "Q. E. D.," "Y in a circle," "Tyne," "Reference."

H. J. PALMER. (No; the coach-house and the stable and the lodge are all to form one block of buildings.)—"Rock." (We cannot undertake to return drawings to corrected addresses. Each drawing must have proper address on the back and name of the author.)—L. J. NEWTON. (See conditions and rules published in BUILDING NEWS for October 25, 1889.)—A. P. FODEN. (See last answer.)

# Correspondence.

## ARCHITECTS' REGISTRATION BILL.

To the Editor of the BUILDING NEWS.

SIR,—Permit me, through the columns of your valuable paper, to state that I sincerely hope the above Bill will ultimately become law, although I believe it will be the means of excluding many who, like myself, now practise as architects without having served under an efficient master, simply because we expressed a taste for drawing, or that circumstances threw such a profession in our way as a means of earning a living. Believing this, in conjunction with one of your recent correspondents on this subject, I cannot agree to the clause which enacts that all now practising as architects, or all those practising from a given date, are to be made "professionals" by "a stroke of the pen and an annual subscription." I cannot, however, concur with the idea that the Bill should become compulsory immediately on its being passed into law, and for this reason: whereas, on the one hand, the retention of the clause referred to

would make "professionals of all men," so to speak, on the other, should the Bill be put into action immediately on its becoming law, the effect would be that all those who have not passed, say, the R.I.B.A. examinations would be made "quacks," and as such would be severely handicapped until they had passed the necessary examinations. This would be, I think, an injustice to those who have been practising for a great many years, and whose abilities are undoubted. What I would suggest is this: That a Bill be introduced embodying the spirit of qualification by examination, such a Bill not to be enforced for, say, two years from the time of its being made an Act. This would give all those who have not as yet passed any such examinations as the R.I.B.A. an opportunity for so doing. I launch this idea with the hope of seeing others' opinions on the matter. I would also add that I hope the examinations will not be of such a nature as to exclude those who do not come up to the standard of first-class architects; but that they shall be of such a nature that principles of design and building construction shall be indispensable, leaving experience to bring the best men to the front.—I am, &c., FRED. W. MCCOSKRIE.  
Grampound-road, Dec. 30, 1889.

# APPLIED MECHANICS FOR ARCHITECTURAL STUDENTS.

SIR,—Having been fully engaged of late, I have paid little heed to the articles under the above title which have been appearing in your paper, until my attention was called to them by a letter from Col. Seddon in your issue of Dec. 27. The errors which he pointed out seemed so extraordinary that I could scarcely believe a well-known man like Mr. Tarn could have fallen into them; but on investigation I find that the case has by no means been understated. The author appears to have forgotten that the stress diagram depends upon the polygon of forces; he has omitted to show how members in compression and tension can be distinguished from one another; and, lastly, he fails to point out with reference to Fig. 10 that, though a wall may be theoretically stable when the resultant pressure falls within the base, yet if it fall too close to one edge the material will probably crush.

Col. Seddon is to be thanked for his watchfulness. Last year he corrected me, though it was long before he convinced me, when writing upon a similar subject, and now he points out where another writer is wrong upon a matter which I worked out correctly then.—I am, &c., G. A. T. MIDDLETON.

SIR,—I would not trouble you again, but being the only one who has been singled out by name, and my correction of Mr. Tarn's wrong theories misrepresented and evaded by him without being heard in my own behalf, in fairness I ought to be allowed to state this fact, as Col. Seddon's letter in your last issue confirms my corrections as being proper, and therefore I need not now repeat them.

I feel sure that a world of students will be grateful for the vigilance of Col. Seddon on their behalf. I say a world of students because your columns are not only appealed to by English youth at home here, but as well as the youth of other nationalities, also by those in America, the Colonies, &c., as I know.

You will, I am sure, understand how important it is that only correct theories, in such a vital subject, should be promulgated through your columns, and impossible and confusing conundrums be avoided.

Mr. Tarn made a reference to his article on "Wind Force, Shoring, &c.," in your volume for 1877. Of course, your young readers in London and the principal English cities may have access to a volume nearly a quarter of a century old, but to expect that those in Colonial and foreign countries, who no doubt form a large and important majority, can have such facilities is absurd, as I know from experience. I learn that Mr. Tarn's theories on that occasion were likewise adversely criticised by many correspondents, amongst whom was Professor Unwin.—I am, &c., ALEX. BLACK.

## CARRIAGEWAY PAVING.

SIR,—It would appear as if the question, "What is the best all-round material for paving town carriageways?" is likely to be seriously considered without delay, and no wonder when

the disappointment as to result of the use of asphalt in the City proper, and wood in the "greater city," for fifteen years has been so patiently borne for the sake of peace and quietness.

At last public attention is fully raised, daily journals are full of abuse of asphalt, and house-owners are calling out for "wood." The City streets are bound to remain as they are till they gradually wear out, although, it may be, both engineer and street committees would not object to try something else. At any rate, no more need be laid down here. Meanwhile, wood is pressing its claim under the auspices of the Horse Accident Prevention Society; but though it is a trifle less noisy, it can hardly be considered less slippery than asphalt, taking all weathers, and our predominating humidity into account.

Beyond the trial of indiarubber abroad and Australian Jarrah wood blocks at home, I do not know of any trials made, or practical suggestion put forth, except "lavish sanding" of a bad surface.

Will the London County Council take up the question?—will the Strand District Board of Works try to find a material the use of which may save their main artery of traffic being in a state of perpetual block for repair, by the time the 20th century dawns, or must we look to that ancient body of experts, "the Worshipful Company of Paviers," which is supposed to be considering essays on the subject sent in pursuant to public advertisement? The verdict of the company, if ever "found" and delivered, ought to settle the material of the future for the next half-century.

I suppose that engineers and road-surveyors will agree that for a sound, economical, permanent road no better material than 6in. by 3in. granite "setts" has been devised, the sole drawback being the noise of iron-tired wheels and hoofs. The first cost is not more, and its maintenance  $\frac{1}{10}$ th to  $\frac{3}{10}$ th of the other kinds. True, it is a trifle slippery in dry weather—with which we are not much troubled in this country.

What I venture to suggest through your columns is, that a level carriage way in cities be paved with 4in. by 7in. "setts" formed of the hardest sandstone to be procured, roughly spauled on top and bed, truly worked at joints, and top arris chamfered to give firmer foothold to the shoes. To bed it upon thin sand (upon sound concrete), joints partly run with asphalt, and partly with coarse lime grout.

When the top is worn down, reverse and relay. The same stones once turned would last three replacements of wood, and have none of the disadvantages of slipperiness; such grit as was caused by attrition would prevent sliding of the polished shoe, which would be roughened thereby. On rising gradients similar "setts," but of Kentish rag, as formerly much used in a crushed form for hilly "macadam" roads.

The root of the evil lies not so much in the road surface as in the mistaken treatment of a horse's hoof by unscientific—if not ignorant—farriers; but the time is not yet arrived when science (?) and nature will be in accord as to this. Without shoes of iron, and with a solid wheel or silent tires, there will be no noise to object to, and then a granite road will be no longer a *bête noir*; but as the strongest surface, will be the best for traffic and for economy.—I am, &c.,  
Hampstead, Dec. 30, 1889. E. W. H.

## A CURIOSITY.

SIR,—How is this for "high"? Who says the New Year doesn't open well for architects?—  
TO BUILDERS AND CONTRACTORS.

THE Guardians of the Wantage Union are prepared to receive PLANS, SPECIFICATIONS, and TENDERS, for the erection of the Workhouse of a Tramp Ward, full particulars of which can be obtained from the Master.

Sealed Tenders, with Plans, &c., to be sent to my Office at Wantage, on or before MONDAY, the 20th of January next, and will be opened by the Guardians on the following day.

EDWARD ORMOND,

Clerk to the Guardians.

Wantage, 18th December, 1889.

Surely the successful competitor deserves a lodging and rations in the Tramp Ward when built!—I am, &c.,  
NOR IN IR.

In the fire which totally destroyed the Royal Palace of Laeken on New Year's Day there is too much reason to fear that all the pictures, many of first-rate importance, the magnificent pieces of sculpture in the Rotunda, and the great library, perished. It is satisfactory to learn that the famous Gobelin tapestry was saved.

## Intercommunication.

### QUESTIONS.

[10191.]—Haddon Hall.—Will some reader kindly inform me of what stone Haddon Hall is built, and who was the architect or architects of the various periods?—MINERVA.

[10192.]—Steaming Windows.—Can any of your readers inform me how to construct a shop window inclosed with a show-case so as to avoid steaming? The lights are now kept out of the windows, and the glass is all right until case is opened, then the warm air immediately condenses on the cold glass. Can anyone say whether they have overcome the difficulty by ventilation or otherwise?—H. T.

[10193.]—Measured Drawings.—Which is the best book to get with hints on measured drawings, especially as to getting the centres for tracery and arches; also the method of measuring mouldings? I have looked in several of your back volumes, and have got a few hints; but many of the questions are unanswered. Could some winner of medal for measured drawings give a short article in your columns, giving particulars and method used?—C. F. B. SHILLITO.

[10194.]—Valuation of Mines.—Can any of your readers tell me of any book that gives information as to the valuation of mining property, more particularly coal mines?—CARBON.

[10195.]—Carpenter's Notice.—A carpenter employed by the day, but receiving his wages at the end of every 24 days: How many days' notice can he legally demand for a dismissal?—UNCERTAIN.

[10196.]—Galvanised Iron.—Are galvanised iron cisterns and pipes injurious to drinking water?—WATER.

[10197.]—Bacon Smoke-House.—I have a smoke-house to build; but never having seen anything of the kind, am quite at a loss how to proceed. The place is to be sufficiently large to smoke twelve sides of bacon at one time. Will some reader experienced in this kind of work kindly give me full particulars, and, if possible, small plan and section?—PERPLEXED.

[10198.]—Diatomite or Kesalghur Bricks.—Can anyone inform me if these are now made and used, and the place, and how made, or where information could be got about them? Dobson, in "Brick and Tile Making," Weale's series, page 21, sec. 16, mentions them.—DIATOMITE.

### REPLIES.

[10175.]—Buttress.—The problem set by "J. W." appears to be intended as an exercise on the articles upon "Applied Mechanics," which are appearing in the BUILDING NEWS. We may presume that the case is a

the direction of T is 18ft., and, putting  $x$  for the horizontal distance B Z, we find  $x$  from the equation—

$$17 \times x = 5\frac{1}{2} \times 18;$$

from which we get  $x = 5.6$ ft. We now have to find the strength of buttress which will prevent the wall being overturned; and we will suppose that the buttress is triangular in section, as FKH, that its breadth is 2ft., and its weight Q, in cwt., is  $18 \times y$ , where KH is  $y$ . The weight Q will act vertically through the point I, where KI is  $\frac{1}{3}$  KH, or  $\frac{y}{3}$ ; and IH =  $\frac{2}{3}y$ . Then the weight of

the buttress in tons is  $Q = \frac{9}{10}y$ ; and the equation from which to determine  $y$  is—

$$(W + P) \left( y + \frac{7}{12} \right) + Q \times \frac{2}{3}y = T \times 18;$$

$$\text{or—} \quad 17y + \frac{7}{12} \times 17 + \frac{9}{10} \times \frac{2}{3}y^2 = 5\frac{1}{2} \times 18,$$

which reduces to—

$$y^2 + 2\frac{2}{3}y - 141 = 0;$$

from which we find  $y = 4\frac{1}{2}$ ft., so that the base KH of the buttress must be at least  $4\frac{1}{2}$ ft. wide to prevent the wall from being pushed over. The collar-beam roofs are very treacherous things to employ, except where the span is small and the pitch is high. I have known walls 2ft. thick and about 12ft. high pushed out of perpendicular by a collar roof of only 20ft. span, and sloping nearly  $60^\circ$  with the horizontal. Tredgold remarks that "failures are often observed from adopting this form of roof."—E. W. T.

[10182].—**Painting Ironwork**.—Good red-lead paint will give satisfaction, and all the rust should be carefully rubbed and brushed off with a hard steel brush.—**CLERK OF WORKS.**

[10184].—**Ventilation for Room Lighted by Gas**.—Insert a good large, well-made, mica-dap ventilator under the ceiling, and connected to the flue from room fireplace, or the connection may be made to the nearest smoke flue in use. The ventilator should have a clear air-space of, at least, 1sq.in. to every 100c.ft. of space in the room.—**W. B.**

[10186].—**Echo**.—Fix a few fine wires across the room. The connections to the walls should be about 14ft. above the floor. The wires can be fixed in the form of a truss—two across the room, with three from end to end.—**W. B.**

[10188].—**Furniture**.—The date of "A. C. W.'s" grandfather's japanned-case clock would be largely dependent upon the design of the case. They were in fashion from about 1770 to 1815. The earlier cases were square or domed at the top. Those of the latter were ornamented with straight or scrolled pediments. The brass dial obtained throughout this period, as did the oak cases. A change of fashion brought in the white or enamelled dials and the mahogany cases. There is no transition between the japanned cases and the mahogany cases; but the reverse is the case with those of oak and mahogany, for the late work cases were banded, moulded, or inlaid with mahogany, which, although a fashionable wood, was very costly. In the latter half of the last century japanned furniture, mostly in the form of cabinets, was very fashionable. This class of furniture was imported from China in the tea-ships. Its introduction into the drawing-rooms of the period created a desire for other furnishings to match, and hence the clock case became a special feature. This japanning of wood as an art was unknown in England; but it was practised to some small extent in Holland. The earliest japanned cases were made in London, and sent with the tea-ships to be japanned in China. This was a costly process, and these ornate clocks could only be indulged in by the opulent of the day. Specimens of these clocks may be found in the mansions of the nobility. They were known by a peculiar Chinese name attached to the lacquer—a name I have not been able to recover. These original clock cases are known to experts, and when in the market realise high prices. The trade done in London in these early cases had its counterpart in Holland; but it was seriously clogged by the time absorbed in the passage out to China via the Cape in the old sailing vessels, in the process of japanning in China, and in the return passage. It was a question of years from the making of the cases to getting the clocks into stock. As may be presumed, the demand exceeded the supply. At this stage the Dutch people put themselves into a position to deal with these large articles of furniture, and they speedily gathered the whole trade into their hands. This may be called the second, or middle, period. This Dutch work was imported in the ready-made case, or English cases were sent over to Holland to be japanned. This stage marked a decadence in art, for, at best, it was only a poor imitation of the earlier or genuine work. The disturbances following upon the Revolution in France was a great blow to this trade in Holland. The import was at one time interfered with, and at another it was altogether stopped. To meet the still-existing demand in this country, japanning was executed in London, no doubt largely by imported or Dutch workmen. This may be called the third or closing period. It was only of short duration, for the business of war absorbed all others. This reminds one of Gilbert's lines—

"Art stopped short  
In the cultivated court  
Of the Empress Josephine."

This art of japanning, as applied to clock cases, has long been dead in England; but it survives in Holland. Those curious on this point may be pleased to learn that this class of work is still performed in Amsterdam. The subject of our grandfathers' clocks is one of great interest. So far as my knowledge extends it is one of our few unwrought or unworked fields. For the above notes I am indebted to Mr. G. W. Dalton, antique furniture dealer, Scarborough, who, in collecting information, on his part was indebted to Dutch traders in London of old standing.—**WM. STEVENSON, The Park, Scarborough.**

Mr. Harry Hems, of Exeter, gave his customary feast to old people on Christmas Day, when about three-score elderly citizens of both sexes were liberally feasted.

## Our Office Table.

The Liverpool Corporation have for some time past been engaged with their town clerk and engineer in drafting a new code of by-laws as to building in the city. The proposals have now been submitted to the Local Government Board, who refused to pass them until certain modifications have been made, one of the more important of these being the deletion of a clause by which it was intended to give the Building Act committee of the City Council power to make concessions at their discretion from time to time on the representation of deputations of ratepayers and others—a clause suggested by the engineer. Copies of the proposed by-laws have been sent to the Liverpool Architectural Society and the local branch of the Master Builders' Association, and the matter has been postponed by the committee of the City Council for a week, in order that these societies may meet and bring before the committee any suggestions that occur to them.

The January issue of the *Architectural Association Notes* contains the following announcement, signed by Mr. Herbert D. Appleton, editor, Mr. R. L. Cox, sub-editor, and Mr. H. W. Pratt, Treasurer: "In consequence of the decision of the committee with regard to the publication of A. A. Notes, we have tendered our resignation, and therefore take this opportunity of thanking our readers for the kind indulgence with which they have received our efforts to make the Notes a success."

EXAMINATIONS of candidates for Plumbers' Registration have been held in Dublin. Mr. R. J. Lyne, United Operative Plumbers' Association of Great Britain and Ireland, and another master plumber were present to represent the London Board of Examiners. The local examiners were Messrs. W. Baird, H. Kerrill, J. Smith, D. P. Curtis, T. W. Little, master plumbers; Messrs. H. Murphy and J. Shiels, operative plumbers; Messrs. Spencer Hart, C.E., City Engineer, P. F. Leonard, C.E., and W. Kaye Parry, C.E., architect. The examinations included tests of practical work and sets of questions relating to materials, construction, and sanitary arrangements. Forty per cent. of the candidates succeeded in passing the examinations. Similar examinations were held in Liverpool, Mr. John Smeaton, master plumber, and Mr. R. A. Nurse, United Operative Plumbers' Association of Great Britain and Ireland, attending to represent the London Board of Examiners, and the local examiners present being Messrs. Lloyd, master plumber, and Heighley, operative plumber; Mr. Edmund Kirby, F.R.I.B.A., Dr. W. Carter, and Dr. W. G. Steeves. Dr. J. Stopford visited the examinations as chairman of the Registration Committee.

The meetings of the Applied Art Section of the Society of Arts will commence on January 28, when Edward C. Robins, F.S.A., will read a paper on "The Relation of the Fine Arts to the Applied Arts." At subsequent meetings papers will be read on February 11 by W. R. Lethaby on "Cast Iron and its Treatment for Artistic Purposes"; on March 4, by James Orrock, R.I., on "The Claims of the British School of Painting to a Thorough Representation in the National Gallery," when pictures by illustrious English masters whose works are not included in the National Gallery will be exhibited by the reader of the paper; on March 25, by H. Arthur Kennedy, on "Glass Painting"; on April 15, by C. Purdon Clarke, C.I.E., on "Modern Indian Art"; and on May 13, by Professor W. C. Roberts-Austen, F.R.S., on "The Use of Alloys in Art Metal-Work."

COMPARATIVELY few newspaper proprietors probably, or indeed, employers in other fields of industry, so agreeably manifested their appreciation of the prosperous condition of their concerns as Mr. J. Passmore Edwards, the proprietor of this journal, the *Weekly Times* and *Echo*, the *English Mechanic*, the *Echo*, &c., who, on New Year's Day, sent a cheque for £1,000 to be distributed *pro rata* among those engaged on the different journals. It need hardly be said that the hearty and thankful acknowledgments of those benefited by this judicious application of the wholesome principle of "profit sharing," unshackled by conditions (which in many cases give with one hand and take away with the other), is accompanied by a hope that such a substantial

token of public approval may be added in shape of increased support of all the journals owned by Mr. Passmore Edwards as may justify his generosity and double the reward of enterprise in all the channels in which vigorously manifests itself.

## MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Royal Academy. "Painting," No. 1, by P. J. E. Hodgson, R.A. 8 p.m.  
Surveyors' Institution. Discussion. "The Tithe Question," 8 p.m.  
Clerks of Works' Association. "Construction of Theatres," by Browne, Carpenters' Hall, 8 p.m.  
Liverpool Architectural Society. "Monumental Brasses," by J. Thornely, 7 p.m.

TUESDAY.—Manchester Architectural Association. "Commission," by Lawrence Booth.  
Glasgow Architectural Association. "Domestic Furniture," by F. M. Mill, 8 p.m.

THURSDAY.—Royal Academy. "Painting," No. 2, Prof. J. E. Hodgson, R.A. 8 p.m.

FRIDAY.—Institution of Civil Engineers. "Irrigation Works on the Cauvery Delta," by Chatterton, B.Sc., Stud.I.C.E. 7.30 p.m.

## Trade News.

### WAGES MOVEMENTS.

DUNDEE JOINERS' DISPUTE.—The master joiners in Dundee have offered to refer the dispute regarding the standard rate of wages to arbitration. The men are said to regard the proposition with favour.

GLASGOW PLASTERERS' LOCK-OUT.—A meeting of operative plasterers was held in the Albion Tavern, Glasgow, on Saturday. A report was submitted, the deputation appointed to meet the employers with the view of again taking steps for a settlement by arbitration, and it was decided to accept of arbitration with the employers and the arbiters selected by them, but only on condition that the operatives be allowed to resume work on the conditions until a settlement is effected. Two three employers have opened their shops on operative's terms, and 160 men are in employment, only 115 remaining on the lock-out roll of the Union.

### CHIPS.

The partnership hitherto existing under the name of Wm. Hudson, Son, and Booth, architects, surveyors, 19, Bennet's Hill, Doctors' Commons, having expired by effluxion of time, Mr. Hudson retires, and Mr. Arthur B. Hudson, C.C., and Mr. A. C. Bulmer Booth, A.R., will continue to practise at the same address the style of Hudson and Booth.

Mr. Edward Monson, jun., A.R.I.E., Grosvenor House, The Vale, Acton, W., has been instructed by the Acton School Board to draw up the erection of the proposed Beulah Park schools, Acton-green, which are intended to provide accommodation for 300 boys, 300 girls, and 400 infants. The site has already been purchased and the work is to be commenced as soon as possible.

A chimney stack for which the claim is being the tallest in North America, although far short of the height of many in Great Britain, has just been completed at Fall River, Mass. 340ft. high above the granite base, and square at the bottom. It is built on the ground the Fall River Ironworks.

The French Minister of Public Works has submitted to the Cabinet Council, the application for the concession to construct a bridge across the Channel, made by the Channel Bridge Company. The French Government has just appointed a committee to examine, in conjunction with Schneider and Hersent, the engineers' plans submitted to the application.

The East Barnet Valley Local Board, invited designs to be sent in competition for proposed board offices, the outlay being limited to £3,000. A large number have been received, and at the last meeting of the board it was decided to submit a limited number to the Works Committee to report upon to a special meeting to be held on the 12th inst.

A recumbent effigy of the late Duke of Albany, executed by Pignatelli at the Queen's command, in the Memorial Chapel at Cannes, has been completed, and will be unveiled by the Prince of Wales during his forthcoming visit to the Riviera.

A meeting of the Association of Public Sanitary Inspectors will be held to-morrow (Saturday) evening at 6 p.m. at Carpenters' Hall, when an address will be delivered by the Rev. Arthur Roberts, rector of Holy Trinity, Windsor, entitled "Homes for the Poor—the Question of the Hour."

## BUILDERS AND ARCHITECTS.

THE connection between the two businesses or arts of building and architecture is not very apparent to some people, who look upon the duties of the architect as being in every respect the same as those of the builder, and occasionally lose sight of the more artistic branch altogether. Exemplification of this indifference among the public may be found in descriptions of newly-erected public buildings, which sometimes appear in the provincial newspapers, which entirely ignore the architect while giving the builder's name, who is thus credited with the design as well as the construction and workmanship. On other occasions they find it convenient to transpose the titles, or to credit the architect with faulty building, bad drains, or any unforeseen accident which happens to create a sensation by falling upon or killing people. The architect is held up to censure when any prince of a Royal house is smitten with fever due to imperfect drainage, or any titled personage falls a victim to carelessness on the part of a building artificer. The proper order or respective duties of builder and architect are then reversed. In private practice the architect has probably many times been called in by a client about matters which would be properly attended to by a builder or plumber, or about questions which pertain more to the duties of a valuer or house agent; the more general or mixed his practice, the more often he is called to render such services. A high-notioned or irate architect is naturally indignant when he is asked to give a plan for the alteration of a back stairs, or to do something which a skilful carpenter could undertake quite as well, perhaps better. Yet a very acceptable number of small commissions would be lost to the ordinary practitioner if he refused these small and sometimes *infra dig.* services. Perhaps if the client were aware of the line which the architect was pleased to draw between his own and the builder's work, he would often hesitate; or, if he knew how unskilful he was in technical matters, he would avail himself of the practical man, and so save the commission. The fact is nevertheless suggestive of the inquiry whether the architect's services in works of a purely practical kind are of value. Happily there are clients who think so; they argue upon some such ground as the following:—"If I do not engage an architect the work may be scamped, as I do not know whether the work is skilfully or unskilfully executed"—sound as far as it goes, for it is the judgment of the professional man that is paid for.

Even those representative bodies who have to deal with public funds in the erection of important buildings sometimes make egregious mistakes in distinguishing between the duties of the two vocations, and in last week's issue we noted a glaring case of this, where the Board of Guardians of Wantage actually advertised for "plans, specifications, and tenders" for the erection of a "tramp ward," the advertisement being addressed "To Builders and Contractors." The guardians have mixed up the two businesses in an amusing manner, and have evidently overlooked the fact that it is no duty of a builder to supply plans and specifications. But perhaps we do the guardians an injustice. They probably thought so unpresenting a structure as a tramp ward might

be more fittingly left to the builder to carry out. Quite as amusing incidents have occurred in the remembrance of many architects, in which their duties and emoluments have been strangely confounded. The line of separation between the two vocations is firmer and stronger than it has been. We all know the time when building and architecture were one, when architecture was building and something more, and when the occupation of constructor or "ingeniator" covered that of the architect. We have outlived this epoch. To-day the two classes are essentially distinct, though each is now and then found encroaching on the other. The builder is now chiefly known as a business or speculative tradesman, who undertakes to erect buildings at the lowest cost and on the shortest notice; the architect as a designer, paid by percentage on the cost. The healthful interchange of mind and hand which once existed is no longer met with; the client must take his chances of getting a substantial and well-designed building. No doubt he thinks, and rightly, that good construction should be the first thing to be looked for.

On this ground is to be explained the employment of builders by many persons. They are thought to be more practical, and to devote personal attention to the work. Those who are in the habit of employing respectable firms, as many large building owners do, tell us that they are sure of having just what they ask for, and no more. The plan is prepared strictly to suit requirements, there is no attempt to make a larger or more ambitious design, the work is done according to an estimate, based on certain prices, and all extras are measured and valued at the same rate. Many large tradesmen have found this the cheapest way of enlarging old or building new premises. In reply to further inquiries, we are told that, as a builder must be employed, it is preferable to have one who takes all the responsibility than to employ an architect who is a second master, the idea being that a direct dealing is more desirable than an indirect transaction. A considerable reason with building owners is cost, and the saving of the architect's commission is a strong motive.

We know a few individuals of this class of clients whose experience has enabled them to draw out their own plans, and to lay their intentions pretty clearly before the builder. An architect has to master the requirements before he can prepare a workable design, and even after modification and amendment it may not be exactly what his client desires. Under these circumstances we have the most favourable conjunction for the practice we have mentioned, especially when the structure belongs to the strictly utilitarian character. Beyond a certain point the architect's assistance may become of very little use; but we must remember that these favourable conditions to dispense with architectural aid are rarely to be found. Plain structures intended for technical uses are within the builders' reach, therefore a large proportion of them go into their hands. Though plain, these buildings require to be substantially constructed. One who knows how to put buildings together, how bond should be laid, the quality of good bricks and mortar and timber, is more likely to produce a sound structure than an architect who has only studied the masses and details. The builder is presumed at least to know more about the anatomy of structure, to study materials and workmanship. We do not deny that in many cases he does. He has been perhaps apprenticed in his younger years to a carpenter and joiner, or has a practical knowledge of some other trade; at least, he has the workshop training, which ought to enable a man to detect good from inferior work. Such a man to an employer who has got an idea of what he wants is all that is necessary.

We have here the *crux* of the matter. Experience in building will convince us that these two things are necessary to produce success—(1) Practical Knowledge; (2) an Idea; and without the combination of the two things it is impossible to produce a successful building. If we consider for a moment the ordinary builder's training, we shall come to the conclusion that it is of a nature that can hardly fit him to embody his views in a concrete form. Skilled probably in one trade, or with a general knowledge of them all—as will be found with those who have served an apprenticeship to a general builder—his mind is too full of the technical details or items of the business to allow him much time for embodying his ideas as to the plan or form a building for any particular object should take. Planning and design are not within his *forte*, and therefore he does not trouble about them. Seldom, indeed, has merely technical knowledge made an architect. An authority, speaking on this point, has declared that the "two or three years at the bench" man was not superior to the man who had never been at the bench at all, but had kept his eyes open. Manual skill in the use of saw, chisel, and plane may be of more value to the quantity surveyor, who has to describe and judge of "labours" of different kinds, but it is of no use to one who has to "invent" or think out a plan, to arrange data of accommodation, such as seats or beds, to study plan and grouping in perspective, or to follow precedent. Manual skill does not enter into these functions of design. The training of the eye in copying plans and designs, or even making tracings of them, is more to the purpose, and it is this kind of work that falls very rarely to young men in builders' offices, except those expressly engaged as draughtsmen. Our large firms of contractors keep their own offices, and some employ an architect and a staff of clerks who are engaged especially on the design of new buildings.

The apprenticeship system in England is at fault. Young men intended for the building trades have not the technical schools of Paris, in which different trades are taught rationally, and where a boy passes through several shops in the first year before he is placed to the trade he has a natural aptitude for. The weakness of English workshop training is that the pupil knows nothing of drawing or practical geometry; he merely acquires the manual knack of using the chisel or plane. In France and Germany each trade has to go through stages of drawing and geometry sufficient for the wants of the workman. Youths are taught to draw from models. Here we have no schools except the Government schools of art or the technical classes, generally very badly supported by building apprentices. The recent reports on the French trades seen at the late Exhibition are unanimous that the English workman is far behind his French brother in design. We are told in one report that any boy in the workshop can give a design for almost anything you ask for, whereas the experienced joiner in England has never been taught drawing of art of any kind. A scandal to our workshops. Why do not our wealthy firms institute classes in connection with their own shops? How few bricklayers can even determine the length of radius for an arch when the width of opening and the rise are given. We have known joiners unable to find the true shape of a jamb when it is splayed with a segmental head. To obtain a development of a curved surface geometrically, or the mode of setting out angle brackets, or of reducing or enlarging mouldings, are problems which often baffle the skill of the joiner. The "rule-of-thumb" method is the only resource. We cannot expect such a training to fit men for the duty of advising employers; but practical experience may help

a man along further than the best scholastic instruction, and we see this proved every day amongst engineers. There are a few who have got an idea, but when they have their practical skill is all they need to obtain employment and to insure success. The inventive engineer is the one who generally manages to get on, and the builder who has the same gift is successful.

Those who employ architects have the acuteness at least to see that without an idea—some scheme or design—the builder's work is so much material and labour mainly misplaced. We are not going to say that the architect is always gifted with the "idea"; he may be without one, yet his knowledge of precedents, his more general training of how to meet requirements is a great deal in his favour, and he can probably, by a few strokes of his pencil, guided by a cultivated mind, stored with the ideas of others, sketch out a design that may more aptly suit the intentions of his client. The preparation of designs by builders is attributable largely to the economic view which the employer entertains—the being able to get what he wants in the most direct manner; and if the profession can show that they are capable of uniting these qualifications of good architecture they can quickly recover their lost ground in the public mind.

#### OLD MASTERS AT THE ROYAL ACADEMY.

A VERY interesting and typical collection of the works of masters of the British School of Painting is to be seen at Burlington House. Though not quite equal to former representative exhibitions of the English masters of portraiture and landscape, Reynolds and Gainsborough, the present winter collection is of more general interest, and contains very fine examples of the Spanish and Dutch schools. A few characteristic works of Sir Joshua Reynolds, Thomas Gainsborough, George Romney, Richard Wilson, Constable and Callcott, and other painters of the 18th and beginning of the present century are hung in Gallery I. An excellent specimen of Reynolds's portraiture is the portrait of Mrs. Payne-Gallwey, daughter of General de Lancey, of New York. The face is in profile, the features sharp and pleasing. As one of the master's unfinished works it is interesting as showing the manner this eminent portraitist worked. A patch of dark background colour is put in to throw up the lady's features. Other portraits are those of William Stirling, in blue coat (17), of Miss Fanny Kemble, afterwards Mrs. Twiss, a pleasant representation of the actress, who was a sister of Mrs. Siddons, in white dress with a blue sash. In the large gallery is a full-length portrait of Frederic Howard, fifth Earl of Carlisle (119); also the Marquis of Townshend; Sir William Chambers, R.A., the architect, a three-quarter portrait, seated at a table before papers, looking towards spectator, with crayon in one hand—a very fine, solidly-painted work, the dark background forming a strong setting to the ruddy complexion, in which background the façade of Somerset House is shown. More poetical are the pictures "Hope Nursing Love," a full-length and graceful portrait of a lady in yellow and drab drapery, with the figure of Love on her lap; and the figure of Puck seated on a Toadstool (162). The beautiful portrait of Viscountess St. Asaph, her playful child undraped in front, is particularly graceful in drawing and colour; the mother is seated on the floor in white dress, and her hair falls in ringlets over her neck. The white pigment on this picture, as on some others, has cracked very much.

Whilst Reynolds's portraits are "souls in faces," his colouring is not permanent. Gainsborough studied simplicity and character. In his landscape there is a sweetness

and serene expression, though subdued, as in his portraits and landscapes in the first gallery (3—6). The full-length figure of "The Housemaid" (3)—a portrait of Mrs. Graham, daughter of the ninth Earl of Cathcart—is full of poetic grace. She holds a broom in her hand, the painting, unfinished, in simple brown. The landscapes of rural subjects are also suffused with a soft, mellow light, the handling crisp and decided. We see also three or four portraits by Romney, one of his best in this gallery being "Miranda in a Boat Propelled by Caliban" (43)—an exceedingly graceful composition in which the pretty face of Miranda and the luminous painting and light are worth noticing. The portrait of Mrs. Chaplin (45) is characteristic of Romney's massive touch in foliage, which forms the background, and generally in these portraits we find the influence of Reynolds's idealistic style in backgrounds as well as treatment, though certainly less brilliant.

The sea-pieces and fishing-boats, by Sir A. W. Callcott, as those of Nos. 2, 21, 47, 44, are calm, clear, and luminous examples. Thomas Creswick, R.A. (14), is represented by a splendid example of a stormy sea-piece and shore, the light spray of the dashing waves set off by dark and angry-looking clouds. Sir Edwin Landseer's "Highland Whisky Still" (12) is a fine specimen of pathos and colouring, also the admirably-drawn dead stag and dogs. "Jocko" is inimitable as a portrait of a dog full of life and animation; so also are the "Intruding Puppies" (16). George Morland, the popular painter of rural subjects, public-houses, and stable life, is seen in a few pictures. His "Farmyard" (11), "Pigstye" (27), and "The Mask" are characterised by nice grouping, tone, and feeling. Next are several works by R. Wilson, R.A., all Claude-like, displaying the classical taste for landscape. Nos. 22, 35, 135, the last a view of Sion House from the Thames, a thorough example of his Italian feeling, tranquil and bathed in sunset warmth. With Reynolds, Wilson, and Gainsborough we can compare Constable's works, of which five are hung. Both the latter painted English scenery, both were Suffolk admirers, and their pictures contrast with the Italian landscape of Wilson. Constable's "Hampstead Heath" (39), "The Chain Pier, Brighton" (55), and "Vale of the Stour" (58) are examples of his work in which we see his rougher, unfinished style of painting, sometimes spotty, as in the Chain Pier, and in others powerful. Fresh, breezy, and showery weather, glistening with wetted foliage is seen in his latter picture, and in his fine landscape of "Dedham Lock" (159), where the sparkle of light is in the foliage. We can only glance at the colour and reflection in Charles R. Leslie's "Mother and Child" (38), the nice grouping and tone in W. Mulready's "Horses Baiting" (28), and his inimitable landscape (33, 34). Pictures by F. Danby, John Linnell (32, 37), and one or two Turners, are also in this gallery. A very brilliant specimen of Turner's portraiture is that of Robert Williams, Captain of the Cumberland Fleet, a three-quarter figure in blue coat, holding a telescope (24). John H. Mortimer is represented by an interior group (26), in which the painter is sketching a mask held by a boy.

Gallery II., as usual, is strong. Pictures by Dutch and Flemish painters, in which are fine specimens of Rembrandt, Jan Steen, Adrian van Ostade, David Teniers, Albert Cuyp, Nicolas Poussin, Ruysdael, Huysum, Hobbema, and other painters, are to be found on the walls. "Rembrandt," by himself, is a characteristic bust portrait, warm in tone (61). By Teniers we have a nice figure-group—"The Seven Acts of Mercy" (100). "A Village Dance" (84), in brown tone, and by Van Ostade, tavern scenes and drinking bouts, as in Nos. 67, 77, 95, in his unrivalled finished style and sharp touch, full of humour and expression. A Dirk Hals re-

presents a "Luncheon Party" (70), and we see a bright flower piece by Jan van Huysum, a river scene by Cuyp, a large larder subject (87) by Paul de Vos, and some landscapes by Hobbema (85—89), Jan Both (112), and Ruysdael; also an animated, crisply-painted little subject by Jan Steen, "Skittle Players." Passing from these finished studies of merry-makings, so full of humour and character, we come to the Third Gallery, where portraits by Reynolds, Romney, pictures by Gainsborough, Sir David Wilkie, some fine portraits by Velasquez, also pictures ascribed to Rubens and Rembrandt, Murillo, and Vandyck, are hung. Of these we can only notice the fine centre group of "The Braddyll Family," by Reynolds (124), a composition in which the painter has given us wonderful expression, and with his usual grace and brilliancy of colour—a picture some time ago bought in at Christie's for 1,000 guineas. The figures are life-size; the lady seated with a spaniel in her lap, and the boy the "Brown Boy," once before seen here. A rather pale-faced portrait is the Countess of Carlisle (122). The pictures ascribed to Velasquez, though lacking the artistic sense of composition, the grace of action and colour arrangement of our great English master of portraiture, are full of colour and marvellous technique, as in the four portraits of Don Balthazar Carlos (134—138), two lent by Sir R. Wallace, one by the Duke of Westminster, and one by the Queen. A portrait of a lady (141) is lent by the Duke of Devonshire. In all these the colouring and brushwork give presumptive evidence of this accomplished Spanish painter's skill. The Earl of Carlisle contributes the "Daughter of Herodias with the Head of the Baptist" (148), ascribed to Rubens—the colouring rich. We must particularly notice the four fine full-length figures of St. Jerome (140), SS. Thomas, Andrew, and Cyril (142—144), said to be by Francesco Zurbaran, a disciple of Michael Angelo. There is much strength and vigour of light and shade in these figures. William Peters' "Children" is a delightful composition (127), full of nice colour. A Vandyck (153), a portrait of John, Count of Nassau-Dillenburg, has a very life-like expression, and one or two fine Rembrandts (147, 151, 152), a mellow-toned and rich "Market Cart" by Gainsborough (163), and a landscape by Sir A. W. Callcott (161), may be noticed.

Space prevents our saying much on the interesting series of portraits from the collections of the Marquis Townshend and the Earl of Suffolk, in the fourth gallery. In these are included portraits of Horace, Lord Vere of Tilbury (177), lent by the former nobleman. Horace was one of the great generals of the "Fighting Veres" who took part in the Cadiz Expedition, and was engaged in the defence of the Palatinate against Spain in 1619, for which services he was raised to the peerage by Charles I. Many portraits of officers who served under him in the Netherlands were painted for Lord Vere, and are by a Dutch painter. Those lent by the Earl of Suffolk are attributed to Daniel Mytens, and belong to the same period. The full-length portraits are in standing attitude on rich Eastern carpets, with the handsome costumes, lace ruffs, full trunks embroidered with gold, or with black dress, cuirass and sash, and other symbols of military service.

The Water-Colour Room is filled with an instructive collection of drawings and models by the late Alfred Stevens, whose work in decoration and ornamental design of various sorts is well known, and whose design for the monument of the Duke of Wellington was erected in St. Paul's Cathedral, for which edifice Stevens prepared a scheme for the decoration of the dome. Among the bold and very spirited drawings we note one for a cove ceiling, and for the decoration of a

groined roof, lent by Mr. Hugh H. Stannus; several designs made for Messrs. Benham and Son; designs for vases and plate, lent by Messrs. Minton; a clever plaster model of a mantelpiece, lent by the Sheffield School of Art; pen-and-ink and water-colour designs for slabs for mantelpieces in china (25-40), displaying invention and nice arrangement. Several studies and sketches lent by Mr. John R. Clayton, a large number by Mr. R. S. Holford, Mr. James Gamble, and the Department of Science and Art are worth notice, particularly Stevens's original sketches for the Wellington Monument in pen-and-ink and in plaster, and a very clever design for the eight panels on the door of the Museum of Practical Geology, Jermyn-street, each panel representing subjects illustrative of the practical applications of that science. The designs for the dining-room decorations of Dorchester House in pen and ink and colour, display a free and tasteful adaptation with a true sense of architectural treatment. The scale model of pendentives, St. Paul's, oil painting on plaster, are lent by Mr. F. C. Penrose. Several life studies and copies of Titian's work in the gallery of the Uffizi, sketches in red chalk for figure decoration, are evidences of the artist's study of the old masters, all remarkably free and classically conceived.

#### ARCHITECTURAL BRICKWORK.— XXVI.

##### ARCHES.

AS these articles are not intended to instruct in the elements of brickcutting and construction, for which purpose there are several manuals well suited to the beginner, it will not be within the course of our remarks to describe the various kinds of brick arches—how they are struck and set out. Our readers are supposed to know the geometry of arches—that there are straight, semicircular, and segmental arches. We may here say that the bricks in an arch generally show their thickness, and as this thickness in an arch with radiating joints must necessarily be at the extrados, the brick has to be cut, or rubbed, to the proper splay with the aid of gauges, to bring it to the wedge-shaped form of a voussoir. Hence, we have "gauged" arches, so called, formed of cut and rubbed bricks, to form a fine joint of lime putty. With commoner kinds of arches, the rough-axed, for example, the diminution or splaying of the bricks is done by the axe, or the unequal widths necessary at the extrados and intrados are thrown into the mortar joint in many cases, and a sort of compromise is struck between the brick and the joint. The joints are wider. What the architect has chiefly to consider is the radius and depth of arch bricks used, for it will be obvious that the less the radius the greater will be the thickness of the joint at the extrados for the same depth of arch. The unfavourable effect produced by an arch of small radius with the bricks laid as headers is easily imagined in a semicircular arch of 3ft. span, where, if the bricks were placed as headers, the joints at the extrados would be as thick as the bricks themselves, or about 2½in., and such a mortar joint would not make a solid or compact arch. In such a case, of course, rings of half a brick in depth are employed, and for all arches of small radius an arch of three rings is generally used. As the radius of curvature increases, the joints become less unequal in thickness—as, for example, in a segmental arch, as shown in Fig. 1, where a 9in. arch, formed with heading bricks, is used without very much diminution or taper of the joints. In short, it should be remembered in designing arches of this description that the greater the difference between the radius and the arch depth, or the radii of intrados and extrados, the less is the

diminution of joint and the better is the arch. In the sketch we give, the bricks are laid as heading bond, or with headers in the intrados; but there are two other modes of building a 9in. brick arch. The bricks may consist partly of headers and partly of stretchers, or be in Flemish bond, every other voussoir being divided into two by a joint. The appearance of the intrados of an arch of this kind would be that of Flemish bond. Another arrangement of the voussoirs is to place them according to English bond, in which headers and stretchers are also used alternately in front, though showing like that bond on the face of the intrados. We shall give further examples in our next article.

##### GOTHIC ARCHES.

As an illustration of forming brick arches of small span under a square straight head or lintel, we give a sketch of a portion of a four-light brick window at Wollerton Manor House, East Barsham, Norfolk (Fig. 2). We have omitted the label moulding to show more clearly the principle of construction. It will be noticed that the four centred arches are composed of radiating bricks, with vertical apex joints; these joints radiating through the triangular-shaped spandrel eyes, and meeting the corresponding joints of the adjacent arch. The arches are, we believe, of moulded bricks, as the principal portions of this notable brick Tudor Manor House are built in that material. Unfortunately,

Wollerton House has fallen into ruin. The windows are all of this Tudor mullioned character. The gatehouse is a very elaborate piece of moulded brick design. We gave a view of the house and some details in a late number of the BUILDING NEWS (Nov. 1, 1889). There are some very good moulded brick panels and string-courses round the hall and bay window, and some examples of brick-headed patterns in the walling.

##### TRACERIED ARCHES.

The same method of constructing ornamental arches is found in Flemish cities. Thus, Sketch 3 represents an arched recess over a window of a hospital at Bruges. The cusped curves can be moulded in the manner shown—that is, the joints made perpendicular to the curve of intrados, or the bricks at the cusplings can be moulded or cut to include the points, and the joint lines drawn to a longer radius, to the centres of the main arcs; but much is left to the ingenuity of the brick-setter. It is very evident that in elaborate arch tracery of this kind, it is better and more practicable to adopt as few centres for the joints as possible to avoid cutting the bricks to awkward shapes, and to avoid using too small bricks at points of contrary curvature.

##### OTHER EXAMPLES.

In sketch 4 we represent a rather elaborate gable front of brickwork, in which traceried work of this description is found over the heads of the windows, and in curved labels

having crockets and finials of carved brick or terracotta. The design is taken from, or based on, a Flemish example, and will show the capabilities of brick design.

#### ARCHITECTURAL ASSOCIATION.

THE fortnightly meeting of the Association was held on Friday evening, Mr. T. E. Pryce, vice-president, in the chair. Messrs. G. Stephenson, J. H. Mann, P. Field, P. P. C. Smith, A. E. Seaman, T. Parker, and W. Stewart were elected members.

#### SPIRES, TOWERS, AND DOMES.

MR. SYDNEY B. BEALE read a comprehensive paper on this subject. It was illustrated by a series of about 260 large photographs, to nearly uniform scale, classified according to treatment, a selection from Mr. James Cubitt's unique collection, lent by the owner for the occasion. Mr. Beale contended that for boldness of conception, grace of outline, and beauty of detail, none could be found to equal the Gothic and even many of the Classic towers and spires of England. In reviewing the history of spires, he should confine his attention to English forms and English construction. The simplest form of spire conceivable was the four-sided pyramid rising from the square tower with its sides parallel to those of the tower and overhanging, then forming slightly projecting eaves upon a corbel table. The central tower of Southwell Minster was an example. In the Romanesque Period the spire had its first true conception. Thäon Church, Normandy, with a masonry pyramidal termination in height about  $1\frac{1}{2}$  diameter, and a steeper one at Valladolid, with a height of  $2\frac{1}{2}$  diameters, undoubtedly embodied the spire principle. In the Early Gothic Period spires obtained a firm hold on English church builders, beginning with the octagonal pyramid and its attendant broaches of masonry springing from the angles of the usually square tower and butting against the splayed side of the octagon. The simple broached spire had an important change; instead of the spire projecting slightly beyond the faces of its tower base, it sprang from a base area entirely within the edges of the tower. This modification opened up a wide field for elaboration, which was taken full advantage of during the Decorated Period. Beginning with the parapet simply, followed by a combination of parapet and broaches; parapet and pinnacles; parapet, broach, and pinnacles; parapets and angle turrets, elaborated again by double pinnacles, and, finally, by the introduction of miniature flying buttresses, springing from the pinnacles or turrets, and abutting against the splayed side of the spire. The Mediaeval builders in this period produced spires of complicated design and elaborate detail, contrasting with the effective simplicity of the early broached spire in a very marked manner. In the early part of the Perpendicular Period the spire had reached its highest state of development and elaboration; spires were constructed from a vertical polygonal drum standing upon a rectangular tower, the surface of the spire was in some instances enriched with cusped panelling. Crockets had free play on the minor turrets and pinnacles at the spire base and up the ribs of the spires themselves. Ornaments and features were crowded on until the zenith of spire design was reached. Then the reaction came, and square towers were once again generally erected without the superincumbent spire. The decline did not occur, however, until some very beautiful examples of each of the different kinds were left to tell their tale. There are some unique combinations of spire and tower in the minor English Mediaeval parish churches, among which may be mentioned an octagonal spire springing from a tower of octagonal plan from base to summit. It would be difficult to specify the date of the erection of the earliest tower in Great Britain, and what were the exact reasons that prompted its erection. Reasoning upon probabilities, we might arrive at a tolerably reliable conclusion in the latter case. The towers of Mediaeval times in secular buildings served for a look-out, as a refuge, and as a place of vantage in troublous times. Archaeologists assured us that the chief ground for erecting the tower was to procure a position for the hanging and ringing of bells. It was, however, asserted that bells of large size were not cast until a date long after large, massive, and high towers had been in existence, a fact which forbade the idea

of bell-raising being the prime cause for ecclesiastical tower building. Certainly there were many causes working together to justify the erection of towers for one or other of the purposes enumerated. In passing, the author noticed the positions of the tower in regard to the body of a cathedral or church. In the southern countries of Europe the tower was frequently detached entirely from the main building—a notable instance being Pisa. The builders of Italy, in erecting a tower, were dissatisfied unless they produced walls 10ft. thick and upwards. The excessive weight of arch construction brought abnormal loads upon the foundations, producing subsidence, and was the chief reason for the isolation of the tower. A settlement (no uncommon thing) due to the great weight of the tower would have entailed disaster and ruin on the cathedral if the tower had conjoined with the general structure. The position over the crossing of a church, as the site of the tower, could scarcely be improved upon, combining, as it did, the essential advantage of a centralised position, all the component portions of the church leading the eye of the observer up to it when seen externally. In view of the modern tendency in church-planning to reserve a large congregational area about the preacher, this central tower afforded every facility for the effective lighting of a portion of the church usually in the dark. Important English examples included the cathedrals of Salisbury, Winchester, Norwich, Worcester, Gloucester, and the Abbey of St. Alban's. Although the central position for the tower possessed many advantages over any other, to the unstable manner in which central towers were constructed had been ascribed their removal to the west end of the nave in more modern instances. The great inconvenience to worshippers entailed by the frequent works of reparation to the central tower brought about its removal to a position less contiguous to the service. The Mediaeval builders did not as a matter of fact erect their central towers with a sufficient regard to economy of material. The western site, on the extremity of the longitudinal central line of the nave, was a very general position for the towers of the parish churches of England. The extremities of the aisles sometimes came right up to the front or west wall of the tower, thus flanking it on both sides one story high, and in other cases the tower stood clear of the main edifice, only joined thereto on the east side. The latter was the proper arrangement for a single west tower, if it was to receive its full significance and importance. There were other less-favoured positions for a tower, of which the least objectionable one was the transept site, north or south. The position for a single tower to be most avoided was that to the north or south of the west front. In England's cathedral towers were exhibited the respective values of each position. Chichester, with its central and detached tower; Ely, with its central and west tower; the two transept towers of Exeter; the three or more towers of Lincoln, Durham, Wells, York, Canterbury, Peterborough, and Lichfield showed combinations of towers that were peculiarly successful in their architectural grandeur. Each country had some peculiarity of arrangement. Italy gave circular and polygonal plans; Germany had the characteristic oblong plan; the towers, usually extending over the whole west end of the church, had been aptly termed narthex towers; while of English towers the great majority were square, or very nearly so, in plan. A tower that relied for effect upon the beauty and variety of the coloured marbles used in its erection and embellishment, could not be criticised from the same standpoint as the tower that relied upon its fenestration for its effect, or the tower that appealed to the eye by reason of its beauty of outline. We might each have our own sympathies directed towards the tower design of a particular age, style, or country. But there were good grounds, patriotism aside, for maintaining that of the towers and spires remaining from the Mediaeval ages, the erection of North-west Europe, and particularly of our own country, must stand in the first rank. Unfortunately, many a beautiful spire had been lost to us for ever, their ruin and fall arising out of ignorant construction and misuse of material, an evil extending into later and even current time. There was in the Norman period and later an extraordinary prevalence of bad construction, to which was traceable the ruins of many a fine abbey. The evil effect of it was even felt in this century. Contemporary church architecture was not much valued unless a precedent could be stated

for the arrangement and each detail of it. Although no constructor would in these days build up the shafted piers of a church or cathedral with a thin casing of stone, of a thickness only sufficient to work its mouldings on, and then shoot in a loose rubble core, resting content with the idea that a pier had been obtained capable of sustaining the heavy superstructure of a central tower, with the thrusts from the contiguous nave arching, still there were many peculiarities of Norman construction and constructive principles of later styles which were even now religiously followed, and which must subsequently be attended with no less disastrous results than those chronicled in the past. The evil prevalent in the building of many of our towers had been the dangerous overloading of foundations and sub-soil bottoms. This was true of the general body of the cathedrals; the weight brought by nave wall on to the foundations approaching very nearly the supporting power of the soil as far as such strength could be accurately estimated. The evil of overweighted foundations was particularly marked in the locality of the towers, and most notably when the tower was over the crossing. Failure not infrequently occurred at the west tower foundations, and it would be useful to inquire what were the agents generally at work endangering the stability of great towers. Such causes as badly-selected materials (as the case of St. Michael's, Coventry) were not now dealt with. First and foremost, the most destructive agent was the great weight of masonry in the tower itself cumbering the ground unduly; this overweight being sometimes further aggregated by a tall spire of heavy construction. Another cause was the presence of timber in the foundations occurring as piles, serving no useful purpose whatever, but subsequently decaying and endangering the superstructure. It was, of course, possible to build very massive masonry to a great height on ordinary soil if the weight of such construction was evenly and sufficiently distributed over the soil. But what had been the method by which the great weight of many towers had been brought on to their foundations? It had been the almost universal rule to carry central towers upon isolated piers, these piers transmitting the pressure upon usually four points of small area, showing, in some cases, a weight of five tons on the square foot, and in others twenty tons. The very nature of a central tower made it necessary to carry the upper portion upon piers; but when this was done, the piers should be joined again into a continuous construction under the ground-level by the building of inverted arches of the same width as the upper tower walls, and further, they should be bedded in a wider base of concrete to sufficiently distribute the enormous pressure. In church work, inverted arches should be built between all the pier bases of the nave arcading, under the chancel arch, and in any other position in which a concentration of pressure was anticipated. With western towers, where there was no reason preventing the carrying down of the walls continuously on to the foundation, the walls, in many cases, were arched over, and carried upon four piers at the angles of the tower, presumably to economise the material so lavishly bestowed above. Bells had always been active agents in tower destruction, both from their weight and from the strains set up by their movement and vibration. The following rule had been published with reference to the necessary thickness of tower walls intended to support bells: The mean internal area of a tower should be one-half the external area, and then, if well built and of good materials, the tower would safely bear as many bells as could be hung on one level. This particular rule took, however, no account of the height to which the tower might be built. Such rules commended themselves to the unwary by their simplicity, and yet the two or three minutes spent in a calculation of such a nature had brought about a world of anxiety, years of regret, and, perhaps, professional ruin. The errors of misjudged construction were not overrated, for examples known to the whole world testified to the danger, and showed that the science of architectural construction was as far behind our excellence in æsthetic design as the medical knowledge was behind the surgical attainments of another profession. The few principles which governed tower buildings might be enumerated very shortly. After having settled the general plan, outside dimensions, and approximate height, the thickness of walls should

be tentatively settled, being dependent upon subsequent calculations. Such preliminary judgment should be based upon the least thickness of masonry requisite for keeping out weather, consistent with forming a secure and complete bond in the material, and other practical considerations, as window treatment, provision of sufficient abutment for vault springings and corbelling. The approximate weight of the structure might then be calculated, and attention was then paid to the influences which were likely to endanger the stability of the tower when properly constructed. Towers and spires were exposed to the full fury of gales. An allowance for the maximum wind pressure should never be omitted when building a spire. The effect of wind pressure upon a tapering Gothic spire was considerably modified by the plan, elevation, and mode of construction of the spire. The inclination of the sides of Gothic spires, varying as they did from about one in five to one in ten, reduced the estimated horizontal wind pressure by 2lb. and 1½lb. respectively on the square foot. This was so small an amount as to be negligible. For an architect's purpose it was unnecessary to find what the reduction was for the vertical slope of a particular spire, as the error was on the side of safety. The plan, if polygonal, reduced the maximum wind pressure from what it would be if acting upon a rectangular-planned spire, a reduction ranging usually from one-third to one-half for plainly-constructed spires. Further, if the spire was built with rounded or other rolls projecting up the ribs at the line of intersection of the planes of the spire, not only was there more surface exposed to the wind, but the edges of the discharge for the wind were cut off, and its impactive force aggravated. From experiments of wind pressure on cellular surfaces composed of test plates with only one, instead of the usual four edges of discharge, the practice was based of adding one-fourth of the registered pressure on the square foot for each line of discharge cut off. The vertical faces of lucernes, or other features, would slightly modify the effective wind pressure upon a spire. Having obtained a careful estimate of wind effect, the approximate weight of the spire with a tentative thickness of material was then estimated, and the subsequent investigation might be either done by calculation of the moments or by graphic resolution. If the investigation were by taking moments, the point about which the forces were estimated as acting should be one-fourth or one-sixth of the least diameter of the spire from the leeward edge, according to its plan. The calculation by moments was advantageous, as it allowed any modification of the weight of the spire necessary to balance the respective moments in foot-tons or foot-pounds of the wind pressure and the spire weight. By this means a reliable spire would be produced possessing the minimum amount of material required for absolute safety and rigidity. Of all the features of spires that did not contribute to its stability the entasis outline was the most prominent. Its introduction to correct a visual delusion surely subverted the important artistic office of the Gothic spire. Who would say that the spire of St. Vincent's, Caythorpe, or St. Helen's, Broughton, Lincolnshire, and many other highly-entased spires, were not artistic failures? For stability the entasis thickened the spire out at the wrong place; by its adoption the base was cut off at the point where, if anything, it should be widened out. On the other hand, such features as broaches, pinnacles, miniature buttresses and turrets added weight and consequent stability to the spire when clustered round its base. To make the investigation complete the further point that should be inquired into was the tendency of portions of the spire to slide on the bed-joints. This action could not possibly occur if the total wind force was less than the normal component of the weight of the spire above any bed-joint, multiplied by the coefficient of friction of the material used in the construction. Failure by crushing should be looked into; the amount of the pressure on the square foot would, in the majority of spires, be greatest at the base, and would vary in disposition and amount according to the distance of the centre of pressure of all the forces acting in and on the spire from the outside edge of the spire. The amount of this pressure upon a unit of area should, of course, be some fraction of the ultimate crushing strength of the material. If the actual pressure was too near the ultimate strength the thickness of the material of the spire should be modified. The

calculation of a tower ran upon the same lines as those for the spire, the modifications being due to the different plan and elevational shape, and the consequent modification of wind effect. The tower had to answer the same demands for stability against overturn, safety against sliding on any bed-joint, and possess a factor of safety against crushing. The total weight brought by the structure upon a unit area of the subsoil should next be estimated, and be within the limit of safety. An interesting inquiry into the western towers' construction of Coutances appeared in the BUILDING NEWS about three years ago. The result arrived at showed an excess of material in those towers to the extent of 1,000 tons beyond the needs of the case. Mr. Beale instanced as a forcible example of an ill-conceived tower the leaning one of Pisa, and by a diagram to a scale of 4·25ft. to the inch, enlarged from a measured drawing, showed how and why this campanile had sunk so seriously on one side. The tower, circular upon plan, was nearly 178ft. high, with an out-to-out base diameter of 50ft., the height bearing a ratio to diameter of 3½ to 1. The walls of lower story were 13½ft. thick, and the upper 9ft. The tower was entirely of marble, which might be reckoned to weigh 170lb. per cube foot. The reduction of the wind effect registered upon a flat surface, due to the circular plan of this tower, was annihilated by the galleries in consequence of their forming cells for the reception of the full force of the wind. In consideration of this a 60lb. pressure had been calculated. The momentum of this force was ridiculously below the strength of the tower, the ratio being as 1 to 5½. The graphic resolution coincided with the calculated margin of safety. Next should be considered the total weight of the tower upon the earth foundation. The tower brought a pressure of 7 tons on the square foot, and at a fair computation the soil, a sandy one, was only capable of sustaining 4½ tons. This fact obviated the need of any further inquiry into the causes of the subsidence. The tower was thrown from 12½ft. to 16ft. out of the perpendicular, and had sunk bodily down some feet in the earth, which had since been excavated away from its plinth. This tower was a unique example of useless masonry overloading its foundations, still standing, as it did, to tell the tale. Many thousand tons of masonry were in the structure which had no business to be there. It could easily be imagined what the fate of the cathedral would have been had the tower been joined to it. The investigations of Canon Moseley, Rankine, and other noted American, French, and German students had now taken a firm hold upon the constructive professions, and these researches were destined to have a far more weighty influence upon architectural construction than had hitherto been the case, tending to produce in our buildings the fullest economy of material consistent with practical needs and lasting stability. Dealing in the last place with domes, the author remarked that very few, if any, were monuments of architectural and constructive skill. In the erection of domes, a field in which scientific knowledge could have such full scope, construction was drifting in a backward rather than in a forward direction. The most recent dome (that for the tomb of the late Emperor Frederick of Germany) decided that the dual construction still held the field. Since the days of Wren there had been seen no legitimate advance in the matter of dome-raising. The cathedral cupola of London was the first of a new race, and in its essential principles one which has been followed by each successive dome constructed of similar materials. The lighting difficulty had not received the attention it deserved as being really the pith of the whole problem of dome construction. Suppose that the convex surface of the spherical dome, as seen from the exterior, was endowed with the importance and dignity consistent with the magnitude of the structure of which it formed part. Then, by 19th-century reasoning, the inside surface of this identical shell was unsatisfactory by reason of the unpleasant visual exertion required to grasp its contour—a disadvantage due to the great distance from the dome to the level of the inside pavement. This defect was undoubtedly due to the system of admitting the light at the wrong place. No dome interior satisfied the canons of artistic taste so completely as that of the Pantheon at Rome, an interior lighted directly from the sky; again, by universal consent, there was not a more inartistic and depressing dome exterior than

that of the same Pantheon at Rome. The evil effect of the flattened appearance of the exterior and its piled-up abutments had been a more powerful factor in modern dome construction than had the principle of admitting the light direct from the heavens. The former had generated the dual and triple constructions of St. Peter's and St. Paul's, and most subsequent domes, while the principle of lighting from the eye of the dome had not been perpetuated with success. It was not suggested that the great value of top-lighting for the dome had not been fully realised, but rather its non-adoption had been due to the concomitant difficulties having proved too much of an obstacle to its realisation. What were these difficulties? In the first place, artistic and even religious sentiment demanded that the apex at the crown of the dome should be surmounted by a lantern erection so as to annihilate the Mohammedan associations attaching to a bald domical sphere. But this very lantern as now built obstructed rather than let in the light. Granted that for architectural reasons the lantern was essential. Then such a lantern ought to be of such a design and of such a size that it conveyed a bright, strong light from the heavens to the dome interior. If this could be done the need for the dual system ceased to exist. The difficulty of carrying a heavy lantern at the apex of a spherical dome had hitherto proved insuperable. It would remain so while stone or brick was relied upon as the sole medium of construction. The materials hitherto composing domical construction, though possessing a full complement of compressive strength, had not possessed that cohesive strength and tensile resistance in sufficient abundance to resist the aggravating bending moments set up by a load at the apex of the dome. The days of masonry and brick domes existing solely as such were numbered, if not even now at an end. And if a dome could be constructed satisfactorily when viewed both internally and externally supporting a lantern erection, then the dual construction which had been the great bar to domical roofing development would be superseded, and an architectural sham be abolished for ever. He proposed to do away with iron chains in domes, and to provide a series of iron ribs radiating from the eye of the dome, formed by a circular metal curb, and abutting upon a similar curb at the base, the whole cross-braced and tied, and fixed upon expansion rollers. By such an erection a framework would be obtained, which could be calculated to resist any bending moment that might be brought upon it by a superimposed lantern, and no thrusts would be transmitted to the drum or abutments. Terracotta would form a very suitable material for casing the whole of the metal framework internally and externally alike; by blocks interlocking, and treated architecturally inside, with over-lapping joints externally. Such a construction would, he believed, produce a dome which, if suitably treated internally, would be satisfactory artistically, and constructively exceedingly economical—proof alike against fire, frost, and the dreaded hand of time.

A discussion followed, in which the Chairman, Messrs. H. O. Cresswell, A. B. Mitchell, and C. H. Brodie took part.

The Mayor of Wigan laid on Saturday the corner-stone of No. 1 viaduct of the Wigan extension of the Manchester, Sheffield, and Lincolnshire Railway. This company constructed a railway from Manchester to Wigan about four years ago; but the terminus was situated in an inconvenient part of the town. The company are extending the railway so that the station can be placed more in the heart of the town. To carry the station from Darlington-street East to Crompton-street a viaduct will be constructed to span the valley of the river Douglas, and it was the corner-stone of this viaduct which was laid on Saturday. After the laying of the stone the corporation were entertained to luncheon by Mr. Braddock, the contractor.

The model for the monument to be placed over the Emperor Frederick's grave, which Professor Begas is executing, has been inspected and approved by the Emperor and Empress. The Emperor Frederick reclines on the sarcophagus, and is dressed in the Cuirassiers' uniform. On his shoulders he wears a mantle, and the hands, crossed on the breast, hold the laurel of victory and a sword. The lower part of the body is hidden by ermine, which falls on to the steps of the sarcophagus. On either side of the head of the sarcophagus, which bears an inscription, sits an eagle. The sides are adorned with reliefs.

MARLING SCHOOLS, STROUD.—NEW HOTEL, ST. HELIER'S, JERSEY.—THE FONT, BEVERLEY MINSTER.—SOUTH PLACE HOTEL, FINSBURY.—NORTHINGTON CHURCH, HANTS.—CHURCH OF ST. GERVAIS, FALAISE.

## OUR LITHOGRAPHIC ILLUSTRATIONS.

## THE MARLING GRAMMAR SCHOOL, STROUD.

THESE schools originated in a gift of £10,000 from the family of the late Sir Samuel Marling, Baronet. This sum has been augmented by an amalgamation of various old charities of the town of Stroud, under a scheme of the Charity Commissioners, which provides both for the erection and endowment of the new schools. The schoolhouse has been planned on the central hall system, and in the head master's house the main idea has been to combine perfect supervision of the boarders with separation from the master's quarters for the sake both of quiet and complete isolation in case of illness. The building is faced with the Quarhouse (local) limestone, dressed with Bath, and backed throughout with brick. The schoolhouse floors are to be of wood block, the lavatories, &c., lined with glazed bricks, and the roofing is of Broseley tiles. Messrs. English and Sons, of Stroud, are the contractors. The heating of the schoolhouse will be by Grundy's hot-air system, with fresh air ventilating stoves in all the class-rooms. The work is being carried out from the designs, and under the superintendence of the architect to the Governors, Mr. W. Howard Seth-Smith, of London. Our illustration is from the perspective which was exhibited in the Academy last year.

## THE GRAND HOTEL, ST. HELIER'S, JERSEY.

THE Grand Hotel at St. Helier's, a view of which we publish this week, is to be built upon the site of the present Marina Hotel. The accommodation provided includes a dining-room, 65ft. by 30ft., a drawing-room, about 64ft. by 24ft., a billiard-room, 36ft. by 26ft., and numerous private sitting-rooms, with about 80 bedrooms for guests. A special feature in the hotel will be hot and cold sea-water baths, a sea-water swimming-bath, and lawn tennis courts in front and rear of the building. The walls of the building will be covered with rough cast in Portland cement. The roofs will be covered with Broseley tiles. The architect is Mr. Thos. E. Colcutt, of 5, Lancaster-place, Strand, whose portrait we published last week.

## THE FONT, BEVERLEY MINSTER.

THE ancient font of this great church has a very fine and elaborately carved cover to it of Late English Renaissance character, and which forms the subject of the accompanying illustration. Whether the work is suited to its position in a Gothic building or not remains a matter of opinion; but at any rate the cover marks a page of history and illustrates a phase of art which, after all the Mediævalists have said, still has many admirers. At the end of the enriched chain supporting the cover and rising over the final of the canopy is a dove with outstretched wings, typical of the Sacrament. The sculpture is very much after the fashion of Grinling Gibbons' work, and the design in a general way is very like the interior fittings of several of our London City churches, as for instance the smaller font cover in All Hallows, Lombard-street. The illustration is from a photograph by Messrs. G. W. Wilson and Co.

## SOUTH-PLACE HOTEL, FINSBURY.

THIS building, now in course of erection, occupies the site of the Temperance Hotel, of which for many years Messrs. Joseph Armfield and Son have been the proprietors. The building has frontages of 65ft. and 93ft. 6in. respectively to South-place and South-street, and is Classic in design. The materials to be used externally are red gauged brick and Monk's Park stone. The building, when finished, will have a lofty and noble appearance. The hotel throughout will be replete with every modern improvement. Whilst great care has been taken to provide every comfort necessary in a commercial and family hotel, undue and lavish expenditure has been avoided. In the basement there is a fine lofty restaurant, 33ft. by 28ft., with smoking-room adjacent. A space of 50ft. by 22ft. has been reserved for commercial show-rooms, the remaining portion being utilised for kitchen and domestic offices. The ground floor is approached from South-place by an entrance lobby 12ft. wide leading into a spacious hall, from which access is gained to the dining, drawing, commercial, billiard, and smoking-rooms. The grand staircase will form a central feature in the hall. The woodwork throughout on this floor will be in American walnut. Some very fine suites of rooms are provided on the first and second floors, and altogether the hotel will include about 150 apartments. A hydraulic passenger lift has been placed close to the principal entrance, working between the basement and fifth floors. The sanitary arrangements will be on the most perfect and modern system. Mr. James Morter, of Stratford, is the contractor. Mr. W. M. Yetts, A.R.I.B.A., is the architect.

## NORTHINGTON CHURCH, HANTS.

THE church at Northington, near Alresford, in Hants, which has just been pulled down, was a modern structure of no particular architectural interest, though it was improved to some extent a few years ago by Mr. Butterfield. The new church, now in course of erection from the design of Mr. T. G. Jackson, stands a few yards from the site of its predecessor. It is being erected at the expense of Lord Ashburton, and will contain sittings for 260. It is constructed of cement concrete, faced internally with Caen stone, and externally with flint-work, inlaid in various traceried patterns. The stone used for exterior masonry is Chilmark, from the Wardour beds. The fall of the ground eastward allows space below the chancel for a vestry, which takes the form of an octagonal chamber with stone vaulting, the ribs of which spring from a central pillar. The seats are of black American walnut, with carved ends. The work, which is now advanced as far as the timbering of the roofs, has been carried out by his lordship's own men under his clerk of works, Mr. Potter, very much to the architect's satisfaction. The carving is executed by Messrs. Farmer and Brindley. We give a view of the chancel and organ.

## CHURCH OF ST. GERVAIS, FALAISE.

THIS ancient Norman town, still partially enclosed within its old walls, and retaining its "Porte des Cordeliers," is most celebrated in the eyes of the antiquary for its Castle, one of the few Norman fortresses remaining in France, the seat of the Dukes of Normandy, and the birth-place of William the Conqueror. The ruin is grand and picturesque, commanding the town from an eminence, where it is isolated on three sides, rendering it a stronghold of the first importance. The donjon keep, rising abruptly from the edge of the precipitous rocks of Norren, is now little better than a mere shell. Here is the cell in which tradition says that William was born, 1027. From the windows a fine view of the Val d'Ante is obtained, where the mills and tanneries crowd the banks of the stream, along the slopes of which, the story says, Duke Robert first espied Arlette, the tanner's fair daughter, washing in the running brook, and became so enamoured of her beauty that she was taken as his mistress, and he continued faithful to her until death separated the lovers. She then became the wife of Herlwin, of Conteville, and the mother of Odo, the fighting Bishop of Bayeux. The chapel here is now occupied as a powder magazine. The "Talbot Tower" is 130ft. high, and is crowned with machicoulis, but the roof was destroyed in the 16th century during the religious wars. It is said to have been built by "Valiant Talbot" between 1118 and 1450, and its walls are 15ft.

thick. The zinc roof on the top is out of all character, and the stone used in 1835, when the structure was repaired, has perished in such a rapid manner as to contrast very unfavourably with the original masonry erected over 400 years ago. Turning to the subject of our illustration, the Church of St. Gervais, we have little account of it to give, and no drawings or sketches of the church seem to have appeared elsewhere. The square central tower is Norman, dating from the beginning of the 12th century; but the roof is modern, like much of the interior work. The Late Gothic of the nave and aisles is thoroughly French, and typically Florid in its detail. The porch has some large iron gates of 18th-century workmanship, which seem to go very well with the building. The fountain, the cross, and the neighbouring houses crowded round the church add to the quaintness of the picture, though churchmen may well take exception to the way in which the sacred walls have been encroached upon by the dwellings erected against the church. The Trinité is a Debased Gothic church, profusely ornamented, chiefly of the 15th and 16th centuries. It stands in the Place de la Trinité, at the foot of the castle.

## CHIPS.

One of the daintiest New Year's souvenirs we have seen is the really charming little ivory calendar and pocket-rule issued to their friends and customers by Messrs. R. Boyle and Son, the leading ventilator manufacturers and engineers, of 64, Holborn-viaduct. It will go into the waistcoat pocket or pocket-book, and is practically imperishable. The gorgeous but yet tasteful black and gold letter of greeting which accompanies the useful little present is a most creditable specimen of fine art printing.

The Tiverton Town Council at their last meeting decided to raise the salary of the borough surveyor, Mr. J. Siddalls, to £250 per annum.

Twenty thousand pounds is the total cost of the new premises, including a large composing-room and foundry at the top of the building at Milford House, in Milford-lane, close to St. Clement Dane's, Strand, erected for the *Daily Graphic*, and Messrs. J. and S. Flint Clarkson are the architects. Necessarily a good deal of special construction has been involved in this work, and the machines are of great size. These are placed in the basement, and are equal to printing 50,000 complete copies of the paper in an hour.

Two memorial windows have just been presented to the parish church, Girvan. They are placed in the south transept of the church, and were designed and executed by Messrs. Ballantyne and Son, Edinburgh.

At the last meeting of the Society of Medallists it was decided to offer prizes of £20 and £5 respectively for medals or models of medals in metal or plaster. Objects in competition should be sent to the secretary, Mr. H. A. Grucher, British Museum, by the 1st of April.

Messrs. Munro and Tubbs hope to begin work for the Cyprus Exploration Fund on the site of Salamis in a few days' time. Mr. and Mrs. Bent are starting for Athens, with a view to an archaeological tour in Asia Minor and Bulgaria.

The Public Free Libraries Committee of the Manchester Corporation have arranged for the delivery of three free lectures at the Reference Library, King-street, on the second Monday in January, February, and March. The first, to be given on Monday evening next, will be on "Secular Architecture," by Mr. Alf. Darbyshire, F.R.I.B.A.; the second on "Ecclesiastical Architecture," by Mr. Percy Worthington; and the last on "Sculpture," by Mr. John Cassidy.

It is announced that the rebuilding of the Palace of Laeken will be begun immediately.

Mr. Samuel Hurst, architect, a native of Bury, but recently in business at Southport, ended his life by taking narcotic poison in a field at Rochdale on Thursday night. He had been unfortunate in business, and a few weeks ago underwent his first examination at the Liverpool Bankruptcy Court. In consequence of his business troubles he had to give up his home, and he and his wife and three children went to his mother-in-law's residence at Rochdale. The second examination in bankruptcy was to have taken place on Thursday last, but Hurst was absent. He was 40 years of age, and was a Sunday-school superintendent. At the inquest held on Saturday a verdict of suicide while in a state of unsound mind was returned.

The first sod of a new brewery was turned at Caerphilly, near Cardiff, last week. Mr. W. D. Blessley, of Cardiff, is the architect; Mr. T. Rees, of Merthyr Vale, the contractor; and Messrs. Llewellyn and James, of Bristol, are the engineers.

## WAYSIDE NOTES.

THE death of Joseph Brentano, at the early age of twenty-seven years, is one of those regrettable incidents in the history of architects of all nations that are, unfortunately, by no means of rare occurrence. Too often we have seen young architects successful in competitions of more than ordinary importance who, through premature decease, have never lived to carry out their designs. In many such instances the cause of death may be directly referred to over-work, or, perhaps, more properly speaking, to the pressure of responsibility on a constitution unable to withstand the strain. I do not know whether in this case we are justified in ascribing the fatality to this cause; but until one hears definitely to the contrary, it is but natural so to do. Whatever may have led to the loss, it is one to be deeply lamented, even though it be to another country's credit that the lost one carried off the laurels in a competition for a work that attracted the attention of the wide world—the reconstruction of the façade of Milan Cathedral.

Yet while lamenting the death of Joseph Brentano, the fact of his youthfulness should be one more encouragement to those young architects who are too prone to bewail their lot, and complain that they have no hope of any marked success until long years have passed over their heads. The incident reminds one of the truth of the assertion that where real talent and energy go hand-in-hand, the age is one of opportunities for the young. With the perfecting and purifying of the architectural competition, those opportunities should increase. I never had much, if any, sympathy with those who are of the melancholy Jacques type of character, believing that such persons find it easier to lie down and complain of the times than to be up and doing, and putting their shoulders to the wheel. The constantly recurring cases where young men, who couldn't grow a beard if they tried, carry off first prizes in competitions, should be enough to give the lie to the complaints of the dissatisfied. Such incidents should serve to show them that the fault is on their side, and that their condition is only to be bettered by superior sobriety, energy, and perseverance, and—in competition work—by a steadfast faith in the righteousness of that principle of "retail" competing which I am never weary of urging upon all.

I had hoped, when last at Canterbury, that the old Kentish minster would long remain innocent of any further operations of the kind that I come to believe more firmly day by day destroys the soul of a building, and leaves but a marble-like effigy, which is not even a truthful semblance of the outward and visible form of the structure as it left the hands of the builders of the Middle Ages. I had hoped that enough had been done in the past at Canterbury to insure the immunity of the building for years to come, and that the "true glory" of the old cathedral might indeed never be ravished. Vain hope! From your laconic paragraph in last week's issue, I learn that the restorer is once more girt about the loins and essaying the war-path with insidious designs specially directed against glorious old Canterbury cathedral. The building, you say, is to be handed over to the tender mercies of our only Mr. Christian. Poor old Canterbury! It is one of those sweet old English Cathedrals to portions of which, when we escape the turmoil of business pursuits, and forget for a moment the prostitution of the architectural muse to 5 per cent., and to cubes, supers, runs, and numbers, we can turn with a sense of happiness and relief that comes over one at the sight of pure old architecture, undisturbed by the unsympathetic "restorative" processes of humanity, but lovely in silent, slow, and natural decay. Being particularly attached to this old building, I feel the more grieved at the news that a few years may now see its moral destruction, and artistic and architectural death—one more old English cathedral enrolled in the now long list of those which "restoration" has caused to appear mere ghosts of their former glorious selves.

Where will operations commence? On the grand old Bell Harry tower? If so, our regret is more poignant. The square belfry at the crossing of Canterbury Cathedral, that rises in such a noble outline, when seen from the quiet Close, and round which the jackdaws wheel and caw incessantly throughout the live-long day in

the green spring-time; has in its architecture acquired that character that only comes to a building, as to a man, with age and a cycle of troublous years. Is not restoring a work of architecture like enamelling, to a smooth and characterless surface, the face of an old man?

I pity the enthusiastic architectural student of the unborn generation. He will have little of the grand old architecture to enjoy and study and love, as these have had who are now passing away—I may, with more accuracy, say who have passed away. Instead of true architecture as left by the old builders, plus the sweet aid of Nature, and her bounteous garlands of lichens, mosses, climbing plants, and wild flowers that blossom in the cracks and crevices of any old building unsullied by modern hands, he will have the cold, dead, mummy-like images left him by those who have, in a worldly sense, flourished on the restoration mania. Surely in that day it will come about that the flickering lamp of Gothic art will go out for ever! If the only examples before the student of to-morrow are to be the buildings that to-day are being restored to the very backbone, void of all architectural, archaeological, and artistic interest—cold and repelling—mere phantoms of a spirit long since passed away, will he not become sad and troubled, and in the bitterness of his heart revile the names of the arch-restorers, while he permanently transfers his affections and sympathies to an alien style. Yes, then, I take it, will be the very death of Gothic principles, and then, as some compensation, perhaps, will earnest attention be bestowed on a manner of well-building where style shall not be the whole end and aim.

About this time of the year an architect has just room to swing the traditionary cat in his offices, and that is all. Through post and by hand have been arriving for some weeks a perfect flood of *almanacs* of one kind or another. The cry is, Still they come! What on earth do the various tradesmen and manufacturers imagine to be the use of a pile of almanacs for the year of grace, 1890? Surely they don't imagine that one can plaster every square foot of the office walls with Mr. Jones, Brown's, or Robinson's almanac, profusely illustrated with various specimens of their manufactures? Is their invention so poverty-stricken that they can think of nothing but almanacs? It is like worked-slippers and the eligible curate. If they can think of nothing original, I give manufacturers of architectural goods a golden hint when I say that for 1891 they might save their money for other purposes than the production of almanacs of all shapes and sizes that have only to be relegated to the wastepaper basket.

I fancy that you hit upon an idea that will prove exceedingly popular and attractive when you commenced the publication of the proposed series of photographs of contemporary British architects. The least inquisitive and curious like to know what Mr. So-and-so who built or designed this or that, or did or said something else, is like. Curiosity, says Burke in his "Essay on the Sublime and Beautiful," has an appetite which is very sharp; but, the essayist truly adds, it is very easily satisfied. The "counterfeit presentments" are, for the most part, excellent and speaking likenesses, several being exceedingly happy. I would send you a sun-picture of my own countenance, only it is really unnecessary; for if you would kindly reproduce a photo of a blanket having four holes burnt therein with a red-hot poker, I feel sure that you would sufficiently convey to your readers the ordinary intelligent facial expression of the ancient

GOTH.

Sir Arthur Blomfield inspected last week the tower of St. Lawrence's Church, Ludlow, which is being underpinned and recessed from his designs, and has since certified that the foundations are now perfectly secure. The work was not, he thinks, undertaken a moment too soon, and the failure originated from a slight movement in the foundations, which most probably occurred very shortly after the tower was built. The cracks might not have got worse had it not been for the shaking of the tower in high winds and the vibration caused by the ringing of the bells.

The memorial stones of a Swedenborgian church in Devonshire-street, Keighley, were laid on Friday. The church will be Gothic in style, and will have a spire. Mr. John Haggas, of Keighley, is the architect.

## NOTES FROM EDINBURGH.

THE story of the past civic year has to record an unprecedented increase in the city rates. Notwithstanding the cessation of the Improvements tax, and an unusual increase in the annual rental (£61,200 as against £39,300 last year), the amount of assessment is 3d. per £1 more than the preceding year. The result is, perhaps, in part to be attributed to lavish expenditure in prosecution of the scheme for improving the Water of Leith, also to the purchase of recreation grounds; but it is evident that there has been injudicious financial management, and the committees responsible for the expenditure are too large to secure the proper consideration of the several matters remitted to their care. The remedy proposed is reduction of the numbers composing each committee, giving to each less to do, in the hope of its being more thoroughly done. Contracts, it is said, would not have been entered on, and much needless Parliamentary expense saved in prosecuting the Water of Leith Drainage Scheme, if more attention had been given to details. A Bill is being promoted for the purchase of the Braid Hills, to provide a golfing ground for golfers who are to be shut out of Burntsfield Links. There are few cities in the kingdom which can boast of such extensive recreation parks and hills, and there are few which need them less. The health statistics of the city are as before, the rate of mortality per thousand having been as low as 11 and as high as 25.

The year has been, like its predecessors, a favourable one for all the building trades. No complaints are heard of want of employment, and the labour market has been steadily improving. The work done has been, much of it, of a kind that will leave its mark on the architecture of the city; there is much of the same still in early stages of progress, and the suburban growth continues, so that the prospects of the coming year are promising. In addition, the Electrical Exhibition building, which is making progress, gives employment to a great variety of trades. A new public school, to accommodate 1,900 pupils, is to be erected in the Sciennes district, not far from one of the first of those built after the passing of the Education Act of 1870. The new asylum is another large undertaking, and the Water of Leith scheme will be the work of years.

The National Portrait Gallery is fast approaching its long-desired completion. The building was opened for the portrait department in July, and has been serviceable also for accommodation of the Art Congress. The eastern section is still in the hands of the masons, who will soon, however, see the close of their labours. The completion of the western and the eastern façades has made a very striking change on the aspect of the edifice, as it has now been decorated with four massive octagonal angle turrets, which have richly crocketed spires. The elevations east and west are altogether different from those north and south, and have a look of the Perpendicular Castellated style, with more of variety in the character and placing of the lights. Many people will prefer this variety to the monotonous arrangement characteristic specially of the principal façade. Here, however, there is much to admire in the fine range of windows and the niches for the statuary. But there is far too much dead wall above it, and a want of emphasis and a look of weakness in the piers of the ground arcade, where there are no impost mouldings, and where some buttressing would have been desirable to give the vertical lines, here altogether absent, or overpowered by the horizontal character of every detail, impressed on the eye by the near or distant perspective. Whilst, however, we might wish to see a little more of the Northern Gothic in the northern façade, it may be that this could be attained only by destruction of its character, as representative of the style in which civic buildings were built in mediæval days, and a gift so excellent and well adapted for its every purpose must not be rashly criticised.

The New Public Library is another interesting subject completed, or nearly so. The plaster work is finishing, and the whole interior will, for the principal rooms, soon be ready for the floor and finishings and furniture. On the ground floor, which comprises a great extent of open cellarage, the steam heating apparatus, now in working order, is located. The apparatus is a very powerful one, and keeps the large interiors at a very comfortable temperature, even in the present condition of the new plastered

surfaces. The ventilating fan chamber is not yet made. The access to the upper floors is mostly in the darkness of borrowed and very defective daylight; but the contrast on entering the reading-room, the lowest of the three principal apartments, is so much the more agreeable. Here there is what may well be designated a great abundance of light, transmitted, on three of the sides, and which, without the dubious supply obtained from the remaining one, would be amply sufficient to light the whole interior. The apartment takes the form of a large central square, with four recesses, separated by lofty pillars and arches. The walls and piers are all lined with white faience and some coloured bordering. The plaster decoration has been designed without that superfluity of detail which makes an interior, when dusty and discoloured, so unpleasant to the eye.

The one defective feature is the east side, where the light is dismal contrasted with the brightness in every other quarter. The light is poor at its best, and at its best only in the early portion of the day, when it will be least of all required.

The departments over the reading-rooms are similar, or nearly so, but with more of ornamental detail. This is specially the case with the upper room, the consulting library, which, with better proportions, has also a large central dome. The hall occupies the best part of the central frontage, with the staircases at either end. The principal staircase is located in a building projected far beyond it, with a view to preserve light from the east side for the reading-room on the floor below. This arrangement has been fatal to the aspect of the George IV. street frontage. The great projection of the staircase tower unavoidably reduces the breadth of frontages at its side; and the Cowgate elevation is the only one that does any justice to the building in the way of giving a fair impression of its magnitude. The ornamental details of the style selected (a kind of French Renaissance) are of a florid type and make matters worse. The tower has its own independent Mansard roof, with an immense frontispiece to its dormer window, out of all proportion to the opening behind, and which at a little distance looks as if some of the larger monuments of the Greyfriars Churchyard had migrated for a more conspicuous position. On the other hand, the central and principal frontage has no visible roof at all, and the large pavilion roof, containing the interior dome, is too far recessed to have any practical value in preserving the unity essential to the designs of so large a building.

The West Kirk restoration has been postponed for a lack of the necessary funds, the actual estimates having exceeded the amount allowed (£14,000) by several thousands more. The design will be curtailed and brought within an expenditure of £17,000. Many think the money would be better spent in cheaply improving and restoring the accommodation of the present church, in keeping with its present rustic surroundings, and in the erection of another church on a site more suitable for its style, and in a better position for the congregation of the Mother Church of modern Edinburgh.

The old church certainly stands too low for effective design with the ordinary garniture of such Classical details, being planted in a hole, with its roof about the level of the eye at Princes-street; and besides this serious disadvantage, the church, as it is, with its naked carcase, is dropsical enough in its proportions for the spire. What the effect will be on the spire when towers and transepts and apse are added has not, perhaps, been duly considered, so that, probably, among contingencies may be reckoned a further sum for the improvement or enlargement of the spire.

The controversy between the R.S. Academy and its critics continues, the latest phase being a long defence on the part of the Academy of its management, and which seems good enough as a reply to any charge of gross mismanagement. Nevertheless the fact remains, that in its long and prosperous career it has done nothing for the artistic encouragement of architecture as a distinct branch of the art it was chartered to promote. The assumption made that the exhibition of paintings owes its pecuniary success entirely to the paintings is not strictly demonstrable or true, for though the architectural section has long been meagre, and devoid of much interest for the general public (for which the Academy may

be in part to blame), there must always be a considerable number to whom they are of more or less importance.

## PRACTICAL ARCHITECTURE WITH DETAILED ESTIMATES.—LX.

By HENRY LOVEGROVE, F.S.I., Surveyor.

ESTIMATE FOR A VILLAGE ELEMENTARY SCHOOL.

SCREENS (Continued).

ft. in.	ft. in.	
2 10 2	8 0	2in. deal moulded both sides framing, four panels high, class rooms 1st floor.
2 20 0	40 0	8. Hatfield's patent roller sheaves, fixed with screws and countersunk holes and four oils.
20 0		Iron runners and fixing in deal flooring, and countersunk holes and four oils.
20 0		Iron guide and fixing and four oils on wood.
2 10 6	11 6	Do., and fixing to brickwork and four oils.
2 2 10 6	6 9 8	Fir wrot. all round, and framed bearer (out of baulk).
2 2 10 6	42 0	Fir, wrot. framed and moulded out of 9in. by 4 1/2in. mould, 14in. girt.
2 9 6	19 0	12. Mitred and returned moulded ends to do.
2 10 6	11 6	Do. as last, but plugged to wall.
2 2 10 2	40 8	2. Mitred and returned moulded ends to do.
2 10 2	4 0	Fir wrot. all round and framed, and twice beaded out of baulk.
3 16 9	9 27 0	Deal wrot. stop, 2in. by 1in., planted.
2 4 0	8 0	2in. deal moulded, fixed sashes in small squares with stout bars.
2 13 0	10 21 8	21oz. glass as before.
2 13 0	26 0	Labour scribing 2in. to brickwork.
2 2 11 0	8 6	6 sashes in 16 small squares each. Size, stain, and twice varnish.
2 2 10 6	4 0	1in. deal wrot. and twice beaded lining, and grounds plugged to walls.
2 9 6	2 0	Deal moulding, 4in. girt.
2 2 10 6	4 0	Size, stain, and twice varnish on framing.
2 9 6	2 0	Add on mouldings.
2 10 6	2 10	Add on dado.
2 13 0	10 21 8	Add on landing.
2 13 0	6 13 0	Add on moulding.
40 6	8 0	2in. deal moulded both sides framing, four panels high, as before, made to slide.
2 50 0	100 0	16 Hatfield's patent roller sheaves, &c., as before.
50 0		Iron runner and fixing in wood flooring and four oils.
2 5 0	10 0	Iron guide, &c., as before, and fixing to wood and four oils.
41 0	11 6	Deduct and add do. fixing to brickwork.
2 40 0	80 0	16. Brass flush handles and fixing to deal.
41 0	11 6	Fir wrot., all rounded and framed bars (out of baulk).
2 40 0	80 0	Fir wrot., framed and moulded out of 9in. by 4 1/2in. moulding, 14in. girt.
41 0	11 6	12. Mitred and returned moulded ends to ditto.
2 41 0	6 18 10	Fir wrot. all round, twice beaded (out of baulk).
2 41 0	82 0	Deal wrot. stop, as before, planted.
40 6	4 0	2in. deal moulded sashes, small squares, stout bars.
8 20 9	90 0	21oz. sheet-glass in small squares.
2 4 0	8 0	Scribing 2in. to brickwork.
4 13 0	10 43 4	16. Sashes in twenty squares (small) size, stain, and twice varnish one side.
4 13 0	52 0	1in. deal wrot., and twice beaded and grounds plugged to walls.
4 13 0	4 0	Deal moulding, 4in. girt.
2 45 2	8 6	1in. deal wrot., with beaded casing and backings to iron stanchion.
2 41 0	4 0	Size, stain, and varnish on framing as before.
2 40 0	323 0	Add on mouldings, &c.
2 40 0	160 0	Add on ditto.
4 13 0	10 43 4	Add on linings.
4 13 0	6 26 0	Add on mouldings.

GOVERNMENT TESTING STATIONS.

THE building operations in America are generally on a vaster scale than those of other countries. In viaducts, lofty tenement buildings, hotels, bridges of iron, the States have held their own at least with respect to scale. To meet these demands upon constructive skill, the Government have thought fit to establish testing machinery. Thus we know what the Franklin Institute of Philadelphia has done, the labours of Professor Thurston in Hoboken, the great testing machines at Watertown Arsenal, yet with these great institutions the results of tests are not readily accessible, or are lost sight of or forgotten. A memorial has been got up by Mr. Cluss and has been accepted by the recent annual convention of the American Institute of Architects to be submitted to Congress, for the purpose of obtaining Government assistance in the establishment of special institutions, testing-stations for building materials. The proposal will no doubt be adopted. The gist of the memorial is that for safe building, static coefficients of strength and elasticity of the materials must be ascertained and controlled whenever a case of importance occurs. The hardness and durability of building stones from newly-opened quarries or new strata

of old quarries should be tested. Combinations of different materials ought to be observed, and the best conditions for using mentioned. An appeal is made to the Federal Government to establish a central head station as a nucleus for harmonious methods and guidance of local institutions to be maintained by States or large central cities, the station to be under professional specialists of high repute. The officials so appointed are to determine the quality of materials submitted by interested parties according to a scale of charges, and in case of litigations these decisions would have weight. Every class of construction and material would be within the scope of the station. We have often expressed our opinion that these testing establishments ought to be promoted or encouraged by every State as a protection to the public, and for the progress of constructive science.

ROYAL ACADEMY ADMISSIONS, JANUARY, 1890.

STUDENTS, UPPER SCHOOL.—A. E. Bartlett, B. F. Fletcher, C. H. Norton.  
STUDENTS, LOWER SCHOOL.—C. W. Baker, C. Bywater, A. J. Edwards, E. Gibson, S. M. Herbert, H. L. Paterson, R. A. Reid, F. D. Smith, J. S. Stewart, G. Streathfield, H. Tooley, A. B. Yeates.  
PROBATIONERS.—H. P. Adams, W. E. Barry, John Beggs, D. Blow, J. Borrowman, A. W. Cleaver, J. B. Elhson, C. Evans, F. Fellowes, D. B. Niven, F. Rhoades, A. Dunbar Smith, D. C. Veazey, H. H. Wigglesworth.

COMPETITIONS.

SHEFFIELD MUNICIPAL BUILDINGS.—We understand that among the six designs selected by Mr. Waterhouse, R.A., in the preliminary competition for the new Municipal Buildings, only one is by a Sheffield firm of architects. Mr. J. W. Pye-Smith, the town clerk of Sheffield, writes us:—"In reply to your letter of the 7th inst., I regret to inform you that my instructions are such that I am unable to disclose the names of the authors or any particulars of the six designs chosen for the final competition."

CHIPS.

A new Fisher-lads' Home has been erected at Grimsby, and special attention has been paid to the ventilation, the extraction of the vitiated air being effected by Messrs. Robert Boyle and Son's latest improved patent self-acting air-pump ventilator.

On Friday, the 3rd inst., Mrs. Fielden, wife of Mr. Thomas Fielden, M.P., opened a sale of work at Slade Church of England School, Todmorden. The school has been raised a story, provision being made for 150 additional scholars. The new floors are of concrete, laid with wood blocks, the total cost being about £700. The work has been carried out by local contractors, under the superintendence of the architect, Mr. Jesse Horsfall, M.S.A., Todmorden and Rochdale.

Extensive alterations have just been completed at Kitwells Park, Shenley, Herts, for Mr. Alfred J. Lambert. The hall has been altered and rearranged in Jacobean style, with new staircase, columns, dado, chimney-piece, and ceiling-beams, all in oak, from designs by Mr. Reginald Pinder, F.R.I.B.A. New parquet floors have been laid down by Arrow-smith and Co. in reception-rooms and hall, and the old fireplaces fitted with Pridgin-Teale and "Nautilus" grates, and oak Jacobean mantels. Messrs. Boff Brothers, of St. Alban's, have had the contract for the house work, and Mr. Carter, of Shenley, that for the stables and farm.

The Edinburgh Town Council have consented to the proposal to convert the old session-house in St. Giles's into a memorial chapel to the late Dr. William Chambers.

A Baptist chapel with schools attached is about to be built at Maryport, from designs by Mr. C. Eaglesfield, of that town.

A new county police-station has this week been completed at New Brompton, near Chatham. It has cost between £3,000 and £4,000, and was built by Messrs. Naylor and Son, from plans by Mr. F. W. Ruch, the county surveyor.

Mr. G. F. Watts, R.A., has presented to the town of Leicester, as the nucleus of art collection, his well-known picture of "Orlando pursuing the Fata Morgana." The Corporation of Leicester have under consideration a proposal for erecting a permanent art gallery in the Town Hall square in the centre of the borough.

Mr. Thomas Miles Richardson, whose water-colour architectural subjects are well known, died on Sunday at his residence, in Porchester-terrace, aged 77 years.

# ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

**BIRMINGHAM ARCHITECTURAL ASSOCIATION.**—At a meeting of the Birmingham Architectural Association, held on Tuesday evening, Jan. 7th, Mr. W. H. Lloyd, vice-president, being in the chair, a paper was read by Mr. F. B. Andrews, A.R.I.B.A., on Pershore Abbey, which was rendered of special interest by the very full manner in which it was illustrated by drawings and photos. Of the history, Mr. Andrews said that much was veiled in obscurity, owing greatly to the fact that fires had been of frequent occurrence in the abbey, destroying, with much else of value, the records of its early years. Various authorities fix the date of its foundation in 604, 681, and 689 A.D., and other dates in the 7th century, of which 681 seems the most probably correct. It was at first dedicated to SS. Mary, Peter, and Paul, and given to the secular canons, but finally became the Benedictine Abbey of SS. Mary and Edburga. Records are found of its restorations, after fires, in the years 1020, 1056, 1102, 1223, 1288, the fire in the last-named year reducing nearly the whole abbey to ashes, together with the town, of which it was the central building. The remains at present existing are the choir, choir aisles, south transept and transept tower, and two small chapels north and south of choir, and sufficient remains of the foundations have been traced to define the form of the Lady-chapel, nave, north transept, cloisters, abbot's lodge, frater, common room, and chapter-house. The south transept, built a few years before the Conquest, is the earliest part of the remains, and the nave and lower part of tower are of the 11th century, the Lady-chapel of the 13th century, and the lantern and belfry stages of the tower of the 14th century. The south transept has a vault of 14th-century work, bearing, amongst others, the arms and rebus of Abbot Newton (1413–1456). The choir has a semi-hexagonal plan at the east end, though the surrounding ambulatory and the Lady-chapel appear to have been square on plan. The tower is of special interest from the very marked resemblance, pointed out by the late Sir G. Scott, which it bears to the tower of Salisbury Cathedral, for though comparatively simple in its detail, the belfry stage is throughout a plainer version of the first stage of the 14th-century work in the Salisbury tower, and the lantern is an absolute translation into the later work of the 13th-century lantern at Salisbury. "The details," says Sir G. Scott, "bear considerable resemblance. The distribution of windows, blanks, and piers is absolutely identical, and so also are the very remarkable bands of quatrefoils," &c. "While speaking, however, of the details as being simplified from those at Salisbury, I must except the internal features of the lantern . . . they are far richer and more beautiful; indeed, I scarcely know of a lantern story so beautiful, and it stands, as far as I know, quite alone in its design." In conclusion, Mr. Andrews mentioned the many interesting buildings which surround Pershore, and which, with the abbey, make the neighbourhood of singular interest to the architect. A hearty vote of thanks was accorded to Mr. Andrews on the motion of the chairman, supported by Messrs. Cotton, Doubleday, Bidlake, and H. R. Lloyd, by a unanimous vote of those present.

**LIVERPOOL ARCHITECTURAL SOCIETY.**—The fourth ordinary meeting of the Liverpool Architectural Society was held on Monday, Jan. 6th. The president (Mr. T. Mellard Reade) in the chair. A paper was read by Mr. James L. Thornely, entitled "Monumental Brasses," with special reference to those of Lancashire and Cheshire.

A scheme has been prepared for the acquirement by a syndicate of an extensive tract of land between Black Rock, Brighton, and Rottingdean, including the cliff and the beach below. Sketch plans have been prepared by Mr. Arthur Loader, of Brighton, for erecting five concrete groynes on the sea-front of the acquired land, and the erection of a seawall with parapet fence below the cliff, the land behind and above being laid out in building plots.

The Théâtre de la Bourse at Brussels, destroyed by fire on Tuesday, was a new edifice, built in 1885, according to all the known rules of insuring safety. It was Renaissance in style, and covered 1,863 square metres of ground. The fire broke out in the heating place under the stage, and quickly reduced the fine building to a carcase.

# Building Intelligence.

**BEARSDEN, GLASGOW.**—Operations have just been begun at the village of Bearsheden for the erection of a Catholic College for Glasgow and the West of Scotland, the gift of Archbishop Eyre, and to be called St. Peter's Diocesan College for the Priesthood. The site extends to about 12 acres. The architects are Messrs. Pugin and Pugin, of Westminster. It will be in the Domestic Gothic style, and, when completed, will provide residential accommodation for about 40 students, with the requisite staff of professors. The buildings will include lecture-halls, professors' rooms, rooms for the students, reception rooms, library, refectory, kitchen, and servants' offices. The total cost of the buildings, together with the laying-out of the grounds, is estimated at £30,000. In the mean time, however, only the college proper is being erected, and the contract for this section of the work is about £18,000. Mr. John Devlin, Glasgow, is the contractor.

**EDGBASTON.**—Less than four years have elapsed since the completion of a considerable enlargement of Edgbaston parish church, but it has been found necessary to enlarge still further. Previously to the last alteration the church consisted of a nave and north aisle under a single gable roof. By the advice of the architect, Mr. J. A. Chatwin, of Birmingham, the form of the roof of the nave was altered so as to allow of the construction of a line of clerestory windows upon each side, the roof of the old north aisle being converted into a lean-to. A new south aisle was erected under an independent gable roof, and a new chancel, chancel aisles, and organ chamber were provided, affording room for a hundred additional worshippers. The present enlargement is effected by the construction of an extra south aisle, the wall and four windows of the older aisle being removed outwards to a line about 16ft. further away from the nave, and an arcade of moulded columns in harmony with those in the rest of the building being substituted for it. The new aisle has also a gable roof of open timber corresponding with its companion. The new aisle will accommodate about 160 persons, and the cost of the enlargement is upwards of £1,000. It was opened on Saturday.

# CHIPS.

A partnership has been entered into between Mr. James Lemon, J.P., F.R.I.B.A., M.I.C.E., &c., of Lansdowne-house, Southampton, and Westminster, and Mr. John H. Blizard, A.M.I.C.E., who for eleven years past acted as a chief assistant to Mr. Lemon. The partnership took effect on New Year's day.

It is understood that the contract for the work to be done at the foot of Thirlmere lake in building the dams and diverting roads, &c., in connection with the Manchester Waterworks, has been let to Messrs. Grisenthwaite, Penrith, and Beatty Brothers, Carlisle. The contract is about £120,000, and in a few weeks it is expected that over 1,000 men will be employed.

The late Alderman Thomas Willington George, of Leeds, who died on the 30th of August last, aged 87 years, leaving personalty valued at £33,920, has bequeathed to the Corporation of Leeds all his oil paintings as a small contribution towards the formation of a public Picture Gallery for that town.

The local board of Handsworth have increased the salary of their surveyor, Mr. E. Kenworthy, from £300 to £400 a year, but no extras are to be allowed in future.

New infants' schools, attached to All Saints' Church, Normanton, Yorks, were opened on Monday. Messrs. Leake and Co., of Normanton, were the builders.

At Glasgow, on Monday, Lord Provost Muir repeated his offer of £20,000 towards the provision of a city art gallery, and was sanguine enough to believe that with the surplus from the Exhibition and substantial subscriptions from Glasgow firms a sum of £200,000 would ultimately be raised.

New board schools, in Westoe-road, South Shields, were formally opened on Monday. They cover a site of 2½ acres, and accommodate 2,003 children. The cost was £15,900, including furnishing, and the outlay was equal to £7 18s. 9d. per head. Mr. J. H. Morton was the architect, and Mr. R. Allinson the contractor.

Mr. Henry Maden has promised to the town of Bacup a public playground, and to give £5,000 for the erection of public baths in the town, if the town council select a suitable site.

# TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

# TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.). To India (via Brindisi), £1 10s. 4d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

# ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation Advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph Advertisement inserted for less than 5s.

# SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING for TWENTY-FOUR WORDS, and Sixpence for every eight words after. All Situation Advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page advertisements and alterations in serial advertisements must reach the office by Tuesday Morning to secure insertion.

# NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XLII., XLVI., XLIX., LI., LIH., and LVI., may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—T. G. S.—A. Co.—E. Le C.—G. and T. E.—M. and S.—G. B.—W. E.—T. G.—R. and R.—J. P.—E. C. H.

J. S. (Discharge of Sewers.)—The remarks in the notice referred to were based on Emil Kuichling's paper in the Transactions of the American Society of Civil Engineers for January, 1889, published at 127, East Twenty-third Street, New York.

# Correspondence.

# THE ARCHITECTURAL ASSOCIATION.

To the Editor of the BUILDING NEWS.

SIR,—At the present time almost all large societies and many of the London volunteer regiments have a Masonic Lodge attached, and it appears to me that the Association might well start and support such a lodge to enable the senior members to meet for social purposes, with or without antiquarian researches, such as are indulged in by the "Quatuor Coronati" Lodge, to which I belong. You, Mr. Editor, will, I am sure, receive and forward to me any communications on the subject.—I am, &c.,

MARK MASTER.

# COMPETITIONS AND GUINEA ENTRANCE FEES.

SIR,—I observe that two competitions are announced where the competitors are asked to plank down a guinea to obtain the particulars. Cannot promoters of competitions understand that it is exceedingly unfair to ask men to bind themselves with a forfeit to do a work of which they know nothing? How can any sane man undertake to prepare an unknown number of drawings of unknown scale and dimensions? How can any architect of experience bind himself to waste two months of his time, and probably £50 besides, in a competition before he knows who will be the assessor? It stands to reason that, if the professional assessor be an eminent Gothic architect, the competitors who do only Classic architecture have no chance; and if the assessor be, on the contrary, a Classic architect,

then the Gothic ones are out of the running. This kind of imposition on the architectural profession is now becoming usual, and it is high time that it be resisted by common action on the part of the victims.—I am, &c.,

LAWRENCE HARVEY.

### REID'S NEW HOTEL, MADEIRA.

SIR,—But a few days since I returned from Madeira. A view and description of Reid's New Hotel appeared in your New Year's number. The description was written before I left England: perhaps, now that I have returned, a few notes may not be without interest. The conditions under which work is carried on in a small island, a backward possession of Portugal (probably the most backward country in Europe next to European Turkey), the simplicity of methods, the difficulty of meeting any fresh conditions that may arise consequent upon the fact that you have no foundry, rolling-mill, brick-works, quarried stone, or indeed any place or magazine in the nature of the large establishments to which we can turn for what we want—all these circumstances bring one face to face with conditions of things more akin to those under which our forefathers worked in this country some two hundred and fifty years ago, and the difficulty of course is to face the requirements of to-day with the old-world people and methods. Outrageous duties are imposed upon everything imported, and consequently in preparing the design this had to be borne in mind at every moment. Cranes, derricks, travellers, &c., are unknown. The stone for walling arrives on the site on donkey-back, and is carried about the building by the men, generally one stone at a time. The stone is a tremendously hard and tough blue basalt, some of which, however, has a natural cleavage. The walls are built with this basalt, and abundance of mortar and stone chips. The mortar, with its strong gritty sand, makes fine and excellent work, thick and solid walls, which one longs to transfer to this country.

This is the ordinary walling of the island. Chimneys, however, are rare; indeed, they are almost an introduction of the chilly Englishman. They are ingeniously made by building in a wood mould, or drum, with a handle on the top. This being perpetually pulled up, after being surrounded with the layer of wall, leaves a circular flue, rather rough inside. Getting such flues round corners or out of the vertical is a troublesome job, and as it was considered necessary that all rooms in the new hotel should have fireplaces, the design had to be humoured accordingly.

The one idea of plan possessed by a Portuguese is symmetry. Architects in the island, were there any, would promptly starve. There are only little journeymen builders, whilst joinery and carpentry are distinct. When a new house is to be built, it is hard to say who will devise it; but it will probably be a copy of Sig. Somebodyelse's house, and the one essential thing is that it shall be symmetrical. In every room every door must have either a door or window opposite.

A small bungalow possessed by a friend of mine had in it about 60 doors, and one room about 12ft. square had four doors opposite four windows. It was impossible to put furniture against the wall in any place.

With the constructive difficulties I was well acquainted before I made my designs; but I was not prepared to find, on my arrival in November last, that the Portuguese superintendent of the works was beginning to revise and improve my plans by introducing the laws of symmetry as understood by him. But so it was.

The concrete and iron balconies were a great novelty. Stone slabs of sufficient size cannot be got, and even if procured would be lifted with extraordinary difficulty and danger.

Sig. Julio, the superintendent before named, who cannot speak or read English, had thought out an ingenious way of constructing the balconies. He proposed to push great rough slabs of basalt between the rolled joists, resting them on the lower flanges, and then buttering up the whole with cement mortar. The weights would have been quite beyond what the iron was calculated to take, and we had to find volcanic scoriae for the concrete, as neither coke nor pumice stone nor brick could be had. The good signor was proposing to leave out the iron struts under the balconies, as he conceived it would appear such a triumph of construction to see

these big balconies hanging out upon nothing at all.

It might be supposed that, where things are so primitive, some tradition of decorative art might survive. There have been, in times past, very good workers in plaster. Many of the ceilings are well designed, and were carried out by hand, and not cast. These plasterers are no more, and have left but the feeblest successors. Pointing to existing examples, one has had to modify designs and live in hope. I will not trouble you with more "experiences," and only trust that should my remarks ever reach the island and be conveyed to the ears of Signor Julio, he will know that I have much to thank him for—more particularly his thorough determination to understand everything before he put it into execution, and then to see it done well.—I am, &c.,

SOMERS CLARKE.

15, Dean's-yard, S.W., Jan. 7.

## Intercommunication.

### QUESTIONS.

[10199].—**Fireproof Floor.**—Would one of my fellow-readers kindly acquaint me of the best means of providing a fireproof floor over a heating-apparatus room? Being confined for head room, would particularly wish it of the least depth, but strong. It has to be laid with paving squares.—BOAZ.

[10200].—**Swimming Bath.**—What is the simplest way of heating water in swimming bath (60ft. by 23ft.)? There is a small furnace for hot-water apparatus for a lecture-hall about 60ft. from end of bath.—PUNCH.

[10201].—**Damage.**—A's house was erected quite 100, and B's, say, 50 years ago. B. has just pulled his house down, and with it A's chimney, which has been supported by said wall. A's wall is only half brick thick, and contains timber, and is now not weatherproof since the removal of B's wall. The flank wall of B's house was, for the first two floors, built on arches and piers forming recesses to A's old wall, which has been used for the last 50 years as the party-wall between the two properties. Is B. liable to be made to rebuild A's wall, as the removal of his wall has caused the damage?—J.

[10202].—**Spring Ballroom Floor.**—Will some experienced person kindly give me full instructions for laying a spring ballroom floor? By this name I mean a floor which has a springing motion.—FLOOR.

[10203].—**Bridge Construction.**—Heating.—Will some obliging reader recommend the best practical books for commencing the study of bridge construction, both masonry and iron? Also any work that may be published on the heating of buildings by hot air and hot water?—SUBSCRIBER.

[10204].—**Crushing Weight of Stone.**—Shall be obliged if some one will kindly state the resistance to crushing of Monk's Park Bath stone and Ancaster stone, when both stones have been similarly tested?—J. H.

### REPLIES.

[10175].—**Buttress.**—Permit me to thank "E. W. T." for his reply to my query, and to ask his help a little further in fully settling the question raised. The case was not a supposititious one, but was an executed example, the said example having buttresses 2ft. 3in. projection, and it was intended to typify the usual and fairly common roof placed over a Gothic chapel. "E. W. T." speaks of collar-beam roofs as being very treacherous, and says no one would think of putting on such a roof. Yet collar-beam roofs are ordinary enough on Gothic chapels, the walls of which (in case of galleries) are some 25ft. high, and the span 50ft. or more, and the buttresses do not seem to project so much as the rule would seem to require for safety. In was in order to determine the necessary projection of the buttress in such cases that I put the question, and to obtain a rule for varying spans and height of walls.—J. W.

[10176].—**Air to Grate.**—The discharge inlet for cold air to ordinary room grate should be under the fire-ribs, and, if possible, at the back. For a common room-grate, a 3in. diameter pipe, or a flue equal thereto, will be sufficient to supply air for combustion, and the supply should be under control by a valve in the pipe or flue. The discharge mouthpiece under the fire should be in the form of a slit at the back of grate, under the ribs. If "J. W." is willing to allow the extra expense of removing the ribs, and get new hollow ribs cast, with a slit in the under side, for the distribution of air, and a proper connection to the pipe or flue be made on the back of the hollow ribs, this method is much better than the former, but more expensive. A supply of fresh air under the fire reduces the cold undercurrent of air at floor level, and, consequently, the extraction of air at the floor level. To provide for proper extraction from the room, "J. W." should insert a back-flap ventilator under the ceiling, communicating with the flue from the fireplace.—W. B.

[10183].—**Renaissance Decoration.**—Drawings of the decorations of the Appartamento Borgia, in the Vatican, were made by Mr. F. W. Woodhouse a few years ago. The Appartamento Borgia was named after its founder, Borgia, Pope Alexander VI. The decorations represent allegorical pictures of the seven sciences; in the lunettes mythical scenes, such as Isis and Osiris, occur, and other subjects are taken from Sacred history.—G. H. G.

[10192].—**Steaming Windows.**—Ventilation is the only remedy for vapour condensing on the glass, and this can be effected by apertures in the window.—G. W. G.

[10193].—**Measured Drawings.**—I do not know of any book that gives instructions for measuring buildings. The centres for tracery and arches are readily

found by taking the width and rise of the arcs, and by these dimensions the centres are determined by geometrical means. The back vols. of the "B.N." contain hints as to drawing mouldings. A small plumb-line vertically hanging from the upper member is the best way to obtain the insets to the different members.—G. H. G.

[10194].—**Valuation of Coal Mines.**—Hoskold's "Engineering Valuing Assistant." Longmans, Green, and Co., London.—A. H.

[10196].—**Galvanised Iron.**—I consider that galvanised-iron cisterns and pipes do not injure water in the least, and are, for that reason, much to be preferred to lead.—H. L.

[10197].—**Bacon Smoke-House.**—I have been professionally connected with several buildings of this kind. Build a chamber with brick sides, of sufficient size to hang twelve sides of bacon, and roof with a hipped roof of slates, terminating in a louvre lantern for the escape of smoke. If "Perplexed" will go to a large bacon-curing establishment he will see at once the simplicity of the construction, or I will give him further details by post.—H. LOVEGROVE.

### LEGAL INTELLIGENCE.

**ALLEGED INFRINGEMENT OF THE BUILDING ACT.**—At the Mansion-house Messrs. Ashby and Horner, builders, were summoned on Monday by Mr. H. M. Lachlan, one of the district surveyors of the City of London, in respect to a certain building now being erected by them in Printers-street. It was alleged that a breach of the 13th section of the Metropolis Building Act, 1855, had been committed. For the defendants it was stated that a very important and novel point of law would be raised in the matter. Mr. Alderman Phillips said as the London County Council were not represented by any legal adviser, he should adjourn the hearing for a fortnight in order that meanwhile the district surveyor might take their instructions. The summons was consequently postponed.

**RE GREEN AND LEE.**—The receiving order in this case was made on the 7th of November, the debtors trading as builders and contractors at Anton-street Works, Hackney, and a statement of affairs has now been furnished, showing gross liabilities £14,372, of which £10,985 are unsecured, and assets £4,545, after providing for preferential payments. The debtors state that they entered into partnership in May, 1887, their capital amounting to £6,764, and they attribute their failure to losses on contracts, particularly in respect of buildings at South Audley-street. The Official Receiver observes that the usual and proper books of accounts have been kept, and the debtors have furnished a statement in explanation of their deficiency, the losses on contracts being estimated at £3,156. The total drawings of the partners for 1888 and 1889 are returned at £2,671.

**DISTRICT SURVEYORS' FEES.**—(Hayward v. Sandon Brothers. *Re* Tavistock-chambers, Hart-street, W.C.)—It will be remembered that in this case Mr. C. F. Hayward, district surveyor of St. George's and St. Giles', Bloomsbury, sued Messrs. Sandon Brothers to recover an amount of £56 5s. as fees due to him as district surveyor, upon the erection of the above premises, which consist of four shops and two sets of chambers on the ground floor, one set of chambers and box-rooms on the basement floor, and eight sets of chambers on the upper floors, all the latter approached through one entrance, and having one staircase, and being let as separate tenements. When the matter was brought before Mr. Bridge, at Bow-street, on October 4th, 1889, he decided in favour of the district surveyor, upon which Mr. Edward Morten, counsel for the defendants, gave notice of appeal, as his contention, and that of Mr. W. Seckham Witherington, defendants' architect, was that sec. 27, rules 1, 2, and 3, applied only as to the "separation of buildings and the limitation of their areas," and not to fees, which are settled under sec. 49, schedule 2, part 1, as not to exceed £10. Leave to appeal was given, and Mr. Bridge suggested that Mr. Morten should draw the case, and when approved by Mr. Hayward, it should be submitted to him for signature. When, however, the parties appeared before Mr. Bridge, Mr. Hayward claimed his fees under sec. 27, rule 2; but his solicitor, in approving the case, inserted also rules 1 and 3. Mr. Bridge objected to rules 1 and 3 being mentioned unless facts could be argued showing what sum Mr. Hayward would be entitled to if rule 3 applied to the question of fees. These could not be arranged, and Mr. Morten pressed the magistrate to state the case under rule 2. Eventually the magistrate declined to state any case, and the summons was dismissed, Mr. Hayward's solicitor advising him not to take one under rule 2. No order as to costs was made.

The town council of Brighton have resolved to pay a fee of £100 to Mr. Philip C. Lockwood, the former borough surveyor, for acting as borough surveyor from the 4th October until the 25th November last, and for his continuous services in London on business of the corporation up to the present time.

## Our Office Table.

SIGNOR GIUSEPPE BRENTANO, the architect who gained the first premium of 40,000 lire in the recent International competition for the reconstruction of the western façade of the Duomo of Milan, died at Brussels last week at the early age of 27 years. We illustrated his prize design for Milan in our issue of December 21, 1888. The late Giuseppe Brentano was the son of Signor L. Brentano, engineer, of Milan, and was a pupil at the Royal Upper Technical Institute in that city. Among other prizes won by him was the Travelling Studentship, awarded by the authorities of Siena in 1885.

A BIRMINGHAM builder writes, asking builders and contractors generally throughout England whether they do not think the time has arrived for them to take steps to guard themselves against losses incurred by the sudden increase in the prices of materials after the contractors themselves have signed their contracts for the work. Brickmakers and merchants of every kind care, he thinks, very little about the builders they supply, who are the only losers. The prices of materials have been raised at least 25 per cent. during the past few months; whereas contracts in many cases were signed one, two, or more years back. It is unjust, he adds, to call upon the builder to pay such increases without the same being allowed to him by the engineer or architect, as the case may be. He recommends that a special clause be added to every contract to the effect that should a sudden rise in the price of materials take place after the builder has signed his contract, a fair proportion of such increase should be added to his tender, and appeals to builders and contractors as a body to take the matter up at once and settle it.

## WATER SUPPLY AND SANITARY MATTERS.

PONTEFRAC T WATERWORKS.—The sinking for these waterworks had last week attained a depth of 107ft. in solid Red Sandstone rock, the yield of the water being about 700,000 gallons per day of excellent quality. At this depth a quicksand fissure was met which passes directly under the permanent buildings, and would always endanger them. Under these circumstances, the engineer, Mr. George Hodson, M.Inst.C.E., of Westminster and Loughborough, has decided to commence a new sinking, the cost of which will be about £1,000.

The trustees and directors of the Crichton Royal Institution for the reception of the insane at Dumfries have resolved to devote £12,000 to the erection within the grounds of a chapel which shall constitute a monument to the founders, Dr. James Crichton, of Friar's Carse, and his wife, who devoted to this purpose a sum of £100,000. Mrs. Crichton died in 1862, having survived her husband for a period of thirty-nine years. The church is only designed to accommodate 350 persons. The plans have been prepared by Mr. Sydney Mitchell, Edinburgh.

A new Home for Crippled and Incurable Children, built at a cost of £5,000, in George-street, Cheetham Hill, Manchester, was formally opened on Monday. The home accommodates 40 children, and stands in grounds of an acre and a half. On the ground floor are two day-rooms, one for boys, the other for girls. Hot-water pipes are carried throughout the whole building. The dormitories are on the first floor, the servants' rooms being above them, and the cooking and laundry quarters in the basement. Near the staircase, and communicating from the top of the house to the bottom, is an elevator. Messrs. Robert Neill and Sons, of Manchester, are the builders, and Messrs. Maxwell and Tuke, of the same city, the architects.

The water works at Darvel, Ayrshire, which have just been completed by the contractor, Mr. Duncan McKerracher, Bo'ness, from the plans of Mr. A. A. Haddin, C.E., Glasgow, were opened on Friday. The supply is procured from the Barr Hill, about a mile from Darvel, and the springs will give twenty gallons per head per day of the population. The storage tank has a capacity for 78,000 gallons, or about two days' supply.

The new produce market at Hereford was formally opened on Wednesday week. It has an area of 1½ acres, and has cost £5,000 for site and £2,000 for fencing-in. The contract for masonry has been carried out by Messrs. W. P. Lewis and Co., and that for ironwork and fencing by Mr. J. H. Morley. Mr. John Williams was the clerk of works.

## MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Royal Academy. "Painting," No. 3, by Prof. J. E. Hodgson, R.A. 8 p.m.

Royal Institute of British Architects. Business Meeting. 8 p.m.

TUESDAY.—Society of Architects. "British Art; as it Was, as it Is, and as it Should Be," by Alfred Fisher. 7.30 p.m.

Institution of Civil Engineers. "Recent Dock Extensions at Liverpool," by George Fosbery Lyster, M.Inst.C.E. 8 p.m.

WEDNESDAY.—Institution of Civil Engineers. Students' visit to the Permanent Sewage Works, at Crossness, of the London County Council. South-Eastern train to Abbey Wood, leaving Charing Cross at 12.20 p.m.

Society of Arts. Discussion on Sir R. Rawlinson's paper on "London Sewage." 8 p.m.

THURSDAY.—Royal Academy. "Painting," No. 4, by Prof. J. E. Hodgson, R.A. 8 p.m.

FRIDAY.—Architectural Association. Discussion on "The Progressive Examinations of the R.I.B.A.," to be opened by Arthur Cates, V.P.R.I.B.A. 7.30 p.m.

Bradford Historical Society. "Some Fragments of Bradford History," by Wm. Scruton.

Architectural Association, 9, Conduit-street, W.—January 17. Discussion to be opened by Arthur Cates, Esq., in a short Paper on "The Examination in Architecture in the Past, Present, and Future." 7.30 p.m.

## CHIPS.

Ald. J. G. Naylar, J.P., builder, of Rochester, was last week presented with a handsome ivory-handled walking-stick by the members of the benefit society connected with his own works, as a token of esteem and respect.

The fourth annual dinner of the Birmingham students of the Institution of Civil Engineers was held on Friday evening, at the Colonnade Hotel, Birmingham. Mr. Charles Hunt, in the absence of Mr. E. Pritchard, president of the branch, occupied the chair, and there were about twenty-five present.

The town council of Doncaster decided on Friday to increase the salary of the borough surveyor from £150 to £200 a-year.

A new edition of the list of members of the Institution of Civil Engineers, corrected to the 2nd inst., being the seventy-second anniversary of its establishment, has just been prepared, from which it appears that the aggregate number of all classes is 5,804. The number at the same date last year was 5,616.

The new wing which has been added to the Sunderland Infirmary in memory of the late Mr. James Hartley was opened on Wednesday week. The wing has been built from designs by Mr. John Eltringham, and cost £13,000.

New premises in Castle-street, Liverpool, were opened by the British and Foreign Marine Insurance Company on Wednesday week. The building has a frontage of five stories in height above the street level, making a total in height to ridge of roof 84ft. Standing upon its granite base and its subbase of Dumfries stone—each a story high—the structure is of terracotta and red bricks. The architects are Messrs. Grayson and Ould, who have designed most of the modern buildings in Castle-street; the builders, Messrs. Jones and Sons, Pleasant-street; the granite is from Messrs. J. and D. Newall's, Dalbeattie, Scotland; the terracotta is from the works of Mr. J. C. Edwards, Ruabon; and the stone and wood-carving were executed by Mr. Edward Griffith, Chester.

Edward Palmer, builder, was summoned by the Wimbledon local board, at the Wandsworth police court, on Wednesday week, for using inferior materials in the construction of a dwelling house. The magistrate imposed two penalties of £5 and 40s. respectively, in addition to the costs.

The new Staffordshire industrial school for girls is now completed. The building, which is situated on the high ground leading from the Lichfield Trent Valley Station to that city, has been built by Messrs. Treasure and Sons, of Shrewsbury, from plans prepared by Mr. Meredith, of Kidderminster. Accommodation for 25 girls is provided.

The Harbour Commissioners of Llanely received at their last meeting a report from Sir A. M. Rendel, who had been consulted with reference to Mr. Kinipple's scheme of forming training banks for the improvement of the harbour, which had been suspended on account of the unanticipated cost. The report, which was adopted, expressed a general concurrence with the plan carried out by Mr. Kinipple, remarking that it is sound in principle and in entire accord with successful precedents elsewhere. So far, however, it had not been pushed forward enough to yield any considerable result, and he recommended that the present training bank be extended 2,500 yards towards Barry Port.

## Trade News.

### WAGES MOVEMENTS.

BIRKENHEAD.—An aggregate meeting of the house carpenters and joiners of Birkenhead and district was held on Friday evening to consider the reply of the Liverpool Master Builders' Association to the proposed alteration of the working hours of the Liverpool and Birkenhead districts. Mr. Jos. Tweedle (chairman of the United Committee of Carpenters and Joiners) presided. Mr. Broster (secretary) read the correspondence that had passed between the men's association in Liverpool and the master builders. The effect of the alterations proposed by the men would be an increase of 1s. 0½d. per week in the wages, and a reduction of 5 hours per week in the hours of labour. The reply of the employers was that they could not concede to the demands. A further letter from the Carpenters' and Joiners' Association stated their firm adherence to the notice of alterations—which expires April 30—and their intention to use all legitimate means to bring the movement to a successful issue. Ultimately it was resolved:—"That this meeting of carpenters and joiners pledges itself to work in harmony with the Liverpool United Trade Committee, and firmly adheres to the notice for alterations of the working rules sent to the Master Builders' Association; and will use every legitimate means to bring the proposals to a successful issue."

BRISTOL.—At a meeting of the members of the Bristol Master Builders' Association, held on Friday evening, it was resolved unanimously that on and after the 28th of March, 1890, until further notice, the wages of the operatives of the various branches engaged in the building trades will be increased ½d. per hour.

DUNDEE.—A meeting of the master joiners in Dundee was held in Lamb's Hotel on Saturday, when it was unanimously agreed, as a compromise, to offer the men 7½d. per hour as the standard rate of pay, thus splitting the difference between the two parties. The strike has lasted four weeks.

Holloway's Ointment and Pills exercise priceless power over Lumbago, all pains of the muscles, nerves, and joints, and quickly reduce all swellings caused by accidental injuries, weakness, or hereditary taints. The intelligible instructions enveloping Holloway's medicine gives full counsel for using it most advantageously for regaining health, strength, and mobility.

## HEATING APPARATUS.

### GRUNDY'S PATENTS FOR HEATING ALL KINDS OF BUILDINGS.

SUCCESS GUARANTEED or No Pay.  
Upwards of 1,000 Testimonials, free on application to  
JOHN GRUNDY,  
30, Duncan-terrace, City-road, London, N.  
WORKS: TYLDESLEY, MANCHESTER.

### DOULTING FREESTONE.

THE CHELYNCH STONE.—The Stone from these Quarries is known as the "Weather Bed," and is of a very crystalline nature, and undoubtedly one of the most durable Stones in England.

THE BRAMBLE DITCH STONE is of the same crystalline nature as the Chelynych Stone, but finer in texture and more suitable for fine moulded work.

Prices, and every information given, on application to CHARLES TRASK and SONS, Doulting, Shepton Mallet, Somerset. London Agents:—Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.

### HAM HILL STONE:

The attention of Architects is specially invited to the Durability and beautiful Colour of this material. Quarries Well Opened; Quick Despatch Guaranteed; Stonework Delivered and Fixed Complete. Samples and Estimates Free.

Address:—

THE HAM HILL STONE COMPANY,  
NORTON, STOKE-UNDER-HAM, SOMERSET.  
London Agent:—  
Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.C.

## THE BUILDING NEWS

AND ENGINEERING JOURNAL.

VOL. LVIII.—No. 1828.

FRIDAY, JANUARY 17, 1890.

## DEFECTS OF CONSTRUCTION.

TO draw up an indictment against contracting builders for errors of construction and omission would be a tedious matter, for we might have to include in the list many points about which the specification and drawings of the architect were not so clear as they ought to be. Probably there is hardly any building of importance erected that can fairly claim to be exempt from errors of some description or the other. Important blunders have been discovered, it is well known; in structures erected for departments of the public service. In the recently-built public offices at Whitehall mistakes of a serious kind have been pointed out; many of our judges and law officers of the Crown have pointed out defects in the new Courts of Justice, and we all know that the Houses of Parliament have ever since their construction been open to almost every kind of charge from architects, engineers, and sanitary authorities for errors of design, planning, construction, drainage, warming, and ventilation. Against its style and excessive elaboration of detail, the earlier critics levelled a vast amount of bitter invective, and they mercilessly attacked its architect; even the commissioners who recommended the stone were criticised, and not unduly if they are responsible for a result which has cost so much to treat by preservative processes. Quite as serious an indictment was laid against the plans first adopted for warming the Houses, and lately the faults of the old drainage system have been made manifest, and new schemes of ventilation and disposal of sewage carried into effect. We do not say that all this criticism was called for; some of it no doubt was prompted by feelings of jealousy, much from a desire to find fault and self-advertise. Every great work is subjected to this ordeal of public opinion; but it survives, as people begin to form a more impartial judgment. What appears to be a mistake at the onset is found to be capable of explanation, or a fault magnified at first beyond its proper importance, begins to assume a less objectionable aspect as time goes on.

Our meaning as regards "defects" of construction must, therefore, be taken in a more restricted sense, and do not include those debatable points upon which theorists, specialists, and artists will always have their opinion and agree to differ. There are some, indeed, who have their "fads" in construction as in other matters, and will carry them out in spite of the common sense of other people. We will first take a few of the commoner defects found in buildings in connection with the chief trades, and we must say that the conventional specification is very often at fault, sometimes at variance, with the best construction or with practical experience. We sometimes read, for example, that concrete is to be thrown from a height into trenches, when it is a matter of experience that a very unequal resistance is offered by this means of concrete laying, as the material is consolidated at certain points only, and the intervening lengths are simply shovelled in or levelled. One strong objection to the practice of throwing is that the heavy ingredients are separated from the fine. The plan now resorted to by careful hands is to deposit and pun the concrete with rammers, not heavily, but lightly. The proper mode of mixing concrete with unslaked and hot, fresh-ground lime, sand, and ballast, and

mixing the ingredients dry, and afterwards just slaking the lime, is not the plan specified, but the old formula of mixing the ingredients all together is still often adhered to. The usual specification clauses scarcely describe the proper methods of wall and arch building, and are confined simply to the kind of bricks and mortar to be used. The imperfection and rottenness of the broken-brick wall are the result of not distinctly specifying that "broken bricks are not to be used except as closers." It will take us too far into detail, however, to pursue this course of inquiry; we will rather, therefore, confine ourselves to the general statement, that in wall construction we find, among other defects, an absence of thought in arranging the points of support. While great care may be taken with long lengths of solid walling, piers, angles, and buttresses, where attention ought to have been directed, are neglected. Failure is generally found to take place at an angle or a pier. Why? Because the "line of pressure" has not received the attention it deserves, or the foot of the buttress—the "toe," so to speak—has had no special study given to it—a point on which all the pressure falls. In piers we find the foundation, or the composition of the masonry or bond often defective, and as they generally carry great weights, a very little disturbance or extra loading is liable to cause settlements of the building. This has been the cause of some of the fractures found in the London Board schools, as in the Salter's Hill School. A large number of the sudden collapses of buildings are attributable to defective pier construction, though the fault has been often laid to the iron girders, if there are any employed. Would it not add much to the value of the architect's plans if the piers and parts of the walling upon which the chief weights rest were distinguished by a darker colour, or notified on the drawings? Builders would then have their attention specially directed to those points.

The exposure of brickwork to the weather is often the cause of injury to a structure; but little attention seems to be paid to it. Owing to the porous bricks, or the want of courses of asphalt, which ought to be inserted at intervals in lofty walls, they become sodden and saturated with moisture, causing dampness. The portions exposed to the weather, like parapets, and chimney stacks and gables, ought to be protected by good lead copings, or asphalt beds. All projecting members, like cornices, are valuable if composed of impermeable materials, with lead or asphalt coverings; but very few buildings have provisions made to guard against the evil of allowing our walls to absorb water which, through the inner warmth, evaporates into the building. We may here dwell on the carelessness with which ground floors are constructed; we mean the absence of maintaining an air current under boarded floors by apertures in the walls. Specifications provide for air bricks in the outer walls; but seldom are they introduced in the inner sleeper walls which carry the bond timber and joists. The basement floor of many a large building in the metropolis, and floors of some public halls which are laid just over the ground, have been relaid after a short time, owing to the rotten condition they were found in. It would be better if architects insisted on solid wood-block floors laid on concrete, carried on iron joisting or brick piers in these situations. That the soil under every building should be drained, and the surface laid with a bed of concrete, is no less important as an item of good building. Before dismissing brick construction we may refer to the very slight attention given by builders and architects to arches, which may become, as we all know, dangerous agencies. A wide, flat brick arch, bearing a heavy load, and placed near the angle of a building, has a tendency to push

out the angle, and to throw the weight or pressure on a very narrow margin of the foundation. Arches in this situation are, if possible, better avoided, and replaced by a girder, unless a good buttress is built to resist the thrust. Then we have mistakes in "anchoring" where beams or girders are anchored to walls. Many structures have been pulled to pieces by iron ties, which go through the wall, and when a fire burns away the joist, or makes the iron sag, tend to throw the wall outwards or inwards. By the substitution of a cast-iron socket, built into the wall, with a lug cast on the seat, over which the joist can be notched, we avoid all the risk and danger of the iron anchor. There should be a free air space at the end of the box or socket to prevent the decay of the timber. These methods are too often neglected or are left unspecified. A great deal may be said about fireproof floor construction, the expedients necessary for preventing the expansion of the iron; but the systems before the architect in the form of terracotta blocks interlocked together, like Blanchard's and other patented systems, leave little to be desired.

Touching stonework, the defects that are chiefly to be met with consist of inattention to the "natural bed" of the stone, improper selection of material, and defective cramping. Numerous edifices in the Metropolis are standing rebukes to the ignorance of their builders under the first of these heads. The rapid decay of the stone in the Houses of Parliament is attributable partly to the wrong laying and partly to the elaborate mouldings, which have retained the moisture instead of shedding it. In buildings where the stone has been set upon its edge lamination has taken place, and decay is found to have made rapid strides. Investigations of decayed stone have generally revealed the fact of the presence of carbonate of lime, the want of projecting members, or defectively-cut mouldings, which have helped to retain instead of throwing off the water. These defective members, by causing dripping on the stones below them, hasten the decay of the stonework under the projections. Unless the binding material of the stone is silicious, there is little hope for any building stone in London and smoky towns. Are the right characters looked for? Every quarry contains good as well as inferior stone. The presence of mica is particularly bad, and so is all material soluble in acids. Instead of a proper selection being undertaken in the quarry, the architect does not trouble; his specification qualifications being deemed sufficient. With regard to proper projecting mouldings, the mistake is often made of not sufficiently undercutting them to shed the water; hence we find many of our public buildings decayed in the flat parts below the cornices, where the water dribbles and soaks into the stone, dissolving out the soluble binding material and leaving lamination or crumbling surfaces. The subject is too extensive to discuss here in all its bearings. In the construction of cornices the proper counterbalance should be obtained if possible, supplemented if necessary by tie-rods or anchoring to the work below. The subject of cramping and dowelling stonework is not looked after as it ought to be; we find iron imperfectly treated used for cramping stones together, or the metal cramps are insufficiently run with lead or brimstone, or covered over with cement. The proper form and material for dowels for connecting together the stones of mullions and pillars is often left to the workman. A Portland cement dowel is probably the best and strongest, and as it can be applied to any irregular mortise or surface, it is preferable to stone, slate, or metal.

In the selection of timber we have the same mistake. It is thought to be no part of the architect's duty to inquire into timber brands and qualities and shipments. A large opportunity is thus left open for introducing

inferior timber into building. In this branch of technical knowledge the architect has to appeal either to books or the practical timber-dealer. To judge timber in the log can only be learned by a long experience, as the age and maturity of the tree have much to do with the matter of sapwood and its position. Questions of seasoning and conversion are equally beyond the ordinary architect's knowledge. We cannot wonder at the large quantity of American spruce and Swedish timber used in place of Baltic goods. In other branches—ironwork, for example—we are apt to rely too implicitly on the manufacturer, and to leave all the constructive designing in his hands, and in contracts for many of our large structures the matter of testing is too often neglected by the architect. Many ordinary defects could be pointed out if our space permitted. We allude only here generally to the imperfect foundations of iron columns, and the want of a spreading base; the inaccurate setting of columns, so that the line of pressure does not truly coincide with the axis; improper sockets or templates for girders, and no allowance for expansion or contraction in the connections. These and very many other defects of building are the results of routine and habit—the acceptance of, and compliance with, specification formulæ which must necessarily leave unnoticed many of the more important points in the execution of the design.

#### THE INSTITUTE PRIZE DRAWINGS.

**THE** Soane Medallion and £50 was offered this time to the best design for a public day school, for 400 boys, on a corner site; but no design was considered sufficiently meritorious. The area of site was a rectangle, 140ft. by 100ft. One of the few good designs is that with motto "Usui Civium Decor Urbium," a classically-treated elevation in sepia, broadly handled, of good detail. The large assembly hall, 80ft. by 30ft., forms the central block on first-floor level, and is lighted by lofty windows; the side wings and back block contain the class-rooms. The entrance is in the centre, and a square gymnasium, well lighted, is on the same axis, with master's and dining-rooms in front. "Non Felix Vir qui acquirebit," with late French Gothic features, shown by a sketchy perspective, has the class-rooms along the side wing, and the lecture-room in the rear. The assembly-hall is over it. A wide recessed entrance under a large archway is one of the salient features of the elevation. "Y Not," in an elaborate Renaissance style, is represented by a firm line perspective, somewhat spotty in effect. The gymnasium and assembly-hall occupy the front block with a square tower-like entrance and staircase, and a projecting wing on the right-hand side for lecture theatre, class-rooms, and laboratory, clever in detail but wanting in pleasing outline. "Vi et Arte" is of Flemish Renaissance character, shown by a brown perspective. "Georgian" is a clever, artistically-drawn set with a bright colour perspective in red brick and rough cast, Dutch in character; the plan having projecting wings, one of them the gymnasium and the other the hall. "Cedric," in Late Gothic, L-shaped, and with a heavy corner block, has merit; the assembly hall is in the front, the class-rooms in the side block. "Alpha" is Classic, drawn in sepia and of the same general plan, A.D. 19th century. A "Student's Idea," "Honeysuckle" are other designs.

The Tite prize, for which five designs have been submitted, hardly calls out the talent we might have expected. "Privacy" is the best design that is hung, and is of an enriched French Renaissance character, with end gateways, the screen being broken up by pilasters, behind which are rooms inclosed by an inner wall arranged on a curve. The

drawings are extremely neat. "Progress," "Italia," "Perrault," "Cinque Cento" are poor in conception and design. The Grissell Medal, for a design for a timber spire, has been responded to by eight designs. "Anno 1889" is certainly a design marked by ability; the outline is picturesque, and the grouped pinnacles at base clever. The author shows an ingenious system of timber framing, and considerable skill in the details of timber construction; the sections are remarkably neat and clear, and indicate the horizontal wind and vertical pressures on the spire. "Science" shows a spire 120ft. high, and a base of 36ft. square, with two tiers of lucerne lights. A very crowded sheet of details, showing connection of timbers, is sent by "Labor ipse Voluptas."

For the Silver Medal and 10 guineas there are several competitors. We notice some capital measured drawings of Cranborne Manor, Dorset, including plans, sections, and elevations, with sepia sketch of the Manor House. The measured drawings of Pluscardyn Priory, Elginshire, by "Wolfe of Badenoch," represent this fine Transitional Norman and Early English edifice. The sketches of Llandaff Cathedral are weak, near which are some pencil sketches, &c., from Ludford Hall, Salop, Salisbury Cathedral, half-timbered houses at Shrewsbury, by Mr. G. F. Bankhart. Mr. John Begg is also a competitor for the Pugin Studentship, and sends some admirable sketches of the rood screen, central tower, and other exterior and interior features of Lincoln Cathedral, including the "Angel Choir." Mr. Detmar J. Blow sends sketches and illustrations of some French churches, very feelingly executed; Mr. H. P. Burke Downing, some beautifully sharp and clear drawings and reproductions from sketches of churches in Kent, Sussex, Herts, &c., brightly executed, and a series of church plans; and Mr. G. Orrell sketches of Furness Abbey. The coloured sketches from Milan, Verona, Padua, Venice, Florence, and other Italian cities, by Mr. Francis Masey, and the clever pencil and ink sketches by Mr. C. E. Mallows are interesting studies. The work of Mr. H. V. Lanchester for the Owen Jones Studentship comprises some clever sketches in colour of mosaic and other decorations from Italian churches; and Mr. A. N. Prentice sends several sketches of merit from Florence, Bologna, Verona, Sienna, Milan, and other Italian places.

The following awards were made on Monday last:—

**SOANE MEDALLION AND £50.**—Like the gold medal for Architecture at the Royal Academy this year, this, the principal prize at the Institute, was not awarded; no design being considered worthy of the honour. Three Medals of Merit were, however, given in the following order:—"Georgian," Mr. F. W. Bedford, Eaton-terrace, Eaton-square, S.W.; "Cedric," Mr. C. Spooner, Margrave-gardens, Hammersmith; "Nineteenth Century," Mr. E. W. Gibson, Belmont Villa, Leicester.

**THE TITE PRIZE AND £30.**—"Privacy," Mr. James Cromer Watt, Bayley-street, Bedford-square.

**THE GRISSELL MEDAL.**—"Anno 1889," Mr. W. Percival, Longton, Staffs. Medal of Merit.—"Labor Ipse Voluptas," Mr. T. F. Pennington, A.R.I.B.A., Bedford-park, Chiswick. Second Medal of Merit.—Mr. J. A. Pile, Silvan-grove, Old Kent-road.

**SILVER MEDAL FOR MEASURED DRAWINGS.**—Motto—"Wolfe of Badenoch," Mr. A. Mackintosh, 14, Richmond-crescent, Bournemouth. N. Medal of Merit, Motto—"Pupil," Mr. J. E. Mowlem, Swanage, Dorset.

**PUGIN TRAVELLING STUDENTSHIP, 1890.**—Mr. John Begg, Bernard-street, Russell-square. Medal of Merit.—Mr. Detmar J. Blow, Park-hill, Croydon.

**GODWIN BURSARY (£50 and Silver Medal).**—Mr. Alfred Arthur Cox, A.R.I.B.A. (Grissell Medallist, 1887), St. George's-terrace, S.W., who will go to America.

There were no competitors for the Institute Silver Medal and twenty-five guineas, offered for an essay on "Fenestration."

**THE ASHFITEL PRIZE,** offered to the candidates passing the compulsory examination with most honours, was won by Mr. H. Baker, 18, Maddox-street, who obtained most marks out of the 79 passed competitors.

The Masonry Class Prizes of £10 and £5 were awarded to Mr. H. A. Woodington, Brixton-hill, and to Mr. A. W. Anderson (Institute Medallist, 1884), Warwick-gardens, Kensington, W.

#### THE SOCIETY OF ARCHITECTS.

**THE** fourth meeting for the present session of the Society of Architects was held at St. James's Hall, Piccadilly, on Tuesday even-

ing, the President, Mr. Robert Walker, of Cork, in the chair. Messrs. James William Frazer, Salisbury-place, South Shields; and Frederick Montague Grafton, 17, The Bund, Shanghai, were elected as members. The Secretary, Mr. G. A. T. Middleton, announced the decease of Mr. John Rhind, of Inverness, who was elected a member in 1887, and on the motion of the President, seconded by Mr. E. Tidman, it was agreed to send a letter of condolence to the relatives. The Secretary also stated that several donations to the library had been received, including a large illustrated folio, "Das Neue Rathaus in München," presented by the author, Professor Georg Hauberrisser, of Munich, hon. member; "The History of Cirencester," by K. J. Beecham, member; and a work by John Birch, member. Votes of thanks were passed to the donors, on the motion of Messrs. H. R. Gough and W. Allport.

The following paper, which was illustrated by between forty and fifty dissolving views from photographs specially taken for the purpose by the author, was read by Mr. A. Fisher, of the School of Art, Gosport, Associate, entitled:—

BRITISH ART—AS IT WAS, AS IT IS, AND AS IT OUGHT TO BE.

A history of the development of Art is, the lecturer remarked, to a great extent, a history of the people. No better indication of the progress of civilisation can be found than in that seen in connection with their art works. In the early periods, the architectural, industrial, and pictorial arts were so closely related that it is impossible to consider one section without the other. All sections at that time were practised by the same individual, and their division in modern times is much to be regretted, as it destroys the greatest interest in art, causing some individuals to confine their thoughts and ideas to one narrow groove from which they often look with scorn on other branches. Our study of British art naturally commences in the pre-historic period, and the question arises, "Had we a style of our own in early times?" After a careful examination of the art remains, it will be seen that there were distinct features peculiar to ourselves, though these were afterwards modified by Eastern influence. An examination of British pre-historic remains shows that, though differing little from those of other races, they had some art feeling, for form at least. These remains may be considered as belonging to the period of Early Celtic art. Respecting the Later Celtic, it subsequently came under various influences, beginning with the Roman invasion. These periods of influence so overlap each other that it is difficult to clearly define their limits. Though, judging from the numerous remains in the country, a large number of Greco-Roman artists must have been imported, their influence on the native art was not very marked, for, on examining the sculptured crosses and illuminated manuscripts, and comparing them with some of the mosaic pavements, such as the one at Brading, we find few traces of Roman art. It was more affected after the introduction of Christianity (in Roman times), which ultimately brought in the Byzantine influence. But it is not improbable that the "mosaic pavements" and other art works found in these "Roman villas" were executed by native workmen under Roman direction. Professor Westwood, in his splendid work on the "Illuminated Manuscripts," considers it to be clearly proved that "at the time when art was almost extinct in Greece, Italy, and other parts of Europe—viz., from the 5th to the 8th century, a style of art had been originated, cultivated, and brought to a marvellous state of perfection in Great Britain, absolutely distinct from that of any other part of the civilised world, was carried abroad by Irish and Anglo-Saxon missionaries, and had some influence on the schools of Charlemagne and others." It is certain that the arts must have been cultivated for ages before they arrived at the perfection shown in their crosses or illuminated manuscripts. Though we have unfortunately no remains in existence of either "sculptured crosses or illuminated MSS." belonging to Pre-Christian times, it is unquestionable that the early Christian "works" were simply copies of so-called heathen examples, for they are ornamented with Pagan signs and symbols; besides, it is well known that ornamented stone pillars were used in pagan religious ceremonies. It is probable that these heathen symbols were adapted to Christian uses

so as to reconcile the people to the new form of religion. The English and Irish stones are generally pillars of a rectangular section, and surmounted by a Latin or wheel cross, while the Scotch stones are usually large and flat, with the crosses sculptured on the surface. The Irish and Scotch stones contain more figures than the English: in some cases the former have figures in all four faces. But in all the execution and variety of the ornament are remarkable features, and the workman seems to have had full scope for his inventive powers. It is not easy to make a selection from the numerous examples of illuminated books, but among the best known are the Golden Gospels of Stockholm, Book of Kells, Book of Armagh, early part of 9th century, and the Book of Durham, or Gospels of Lindisfarne, close of 7th century. The first named of these three was executed in the 6th or 7th century, and having been stolen by a Scandinavian force on one of their pillaging excursions, was bought from them, at a great cost, by a Saxon earl (Alfred) and his wife, and deposited at Canterbury. It did not, however, stop there, for it was found on the Continent in the 17th century, purchased by a Swedish gentleman, and given to the Stockholm Library, where it now is. In the illustrations of this volume the treatment is ornamental rather than natural, without any relief, and very little shadow in the figures: the surroundings are architectural. The "Book of Kells," traditionally said to have belonged to St. Columba, is unquestionably the most elaborately executed MSS. of early art now in existence. The "Book of Durham," executed at the close of the 7th century, may be seen at the British Museum. It is a small volume, splendidly illuminated. The authorities spent £150 on its binding. All the figures of these times, though possessing native originality, were more or less influenced by the Byzantine type. This may be seen on comparing the examples just named, with one or two known to have been executed under that influence, such as those at Chichester, brought from Selsey when the bishopric was removed to Chichester; and also with the figures in the Byzantine pictures in our National Gallery. Many of the figures in their illuminated manuscripts, however, are very rude, and all are more remarkable for their brilliancy of colouring and gilding, than for the intelligence of the faces or the accuracy of the drawing. Among the rudest examples are the MSS. of St. John's College, Cambridge, and at the Library of St. Gall, in Switzerland. The Saxons, before their settlement in England, were too much given to warfare to have cultivated a taste for art; later on, however, they adopted the British style, adding to it some modifications received by them from the Byzantines, but all so-called Anglo-Saxon work is really Late Celtic. The invasions of the Norsemen were not without their influence on the native art, consisting mainly of the grafting or adoption of the forms and symbols of their religion on those of the Christian religion in order to bring them within its fold. The Crosses at Kirk Braddon in the Isle of Man, and the Font in Kirk Bride Church, Cumberland, are considered good examples of this type. Representations of the gods of the Vikings are here used as an introduction to, and explanation of, the Christian form of worship. But amid all these changes the native art retained its principal features, and remained truly a Celtic or British style down to the time of the Normans. After this date it gradually deteriorated and practically became extinct in the 15th century. With the Norman invasion came a gradual change. Norman art itself at first was of a very rude type, and was used mainly in the embellishment of their churches. It had now become almost a universal practice to decorate their churches with sculptured and painted figures and ornament. The forms used in the ornamentation were very simple, and the colouring chiefly used to give effect to the ornament. From the 13th to 16th centuries the art efforts were mainly expended on the walls of the churches in the shape of pictures of Scripture scenes; but there are records of the reigns of John and Henry III. showing that these monarchs also spent large sums in the decoration of their palaces, chiefly by foreign artists. It was during Henry III.'s time that the first bronze statues were cast in England. The incised figure at Brading Church, Isle of Wight, and the rood screen at Ranworth Church, Norfolk (published recently in the *Building News*), are fairly representative types of the works executed during this period. They

both belong to the 15th century, though ruder work is often met with. There are a few portraits of the 15th century to be seen at Windsor Castle. A revival took place in Henry VIII.'s time. He attracted some foreign artists to his court, one of them being the famous Holbein, who painted the portraits of many court personages, including five of Henry's wives, among them being Anne of Cleves. Some of these portraits may be seen at Hampton Court Palace, but it is singular that we have none of his works in the National Gallery. The style of Holbein was rather of a sombre and heavy character, and he certainly does not appear to have flattered his sitters. Art flourished much more under Mary than under Elizabeth, the latter reign, in fact, is almost a blank in the history of art. But Charles I. generously encouraged all men of ability, and devoted large sums to the formation of an art collection; among others he purchased the famous Raphael Cartoons. He induced Rubens and Vandyck to settle for a time in this country, laying a foundation which afterwards bore remarkable fruit in spite of the disastrous check given to art during the Commonwealth. Both Rubens and Vandyck are well represented in the National Gallery and also at Hampton Court. With the death of Charles, art for a time was banished, the splendid collection he had formed was ruthlessly broken up by the Parliamentarians. Valuable pictures, which now grace foreign galleries, were given away or sold for trifling amounts; not only were the pictures scattered, but many fine paintings and sculptures on the walls of the churches were scandalously destroyed or whitewashed over. The art culture of the nation was seriously checked under the Commonwealth. With the restoration of Monarchy came the gradual restoration of art, though this is not, perhaps, due to Charles II. so much as to those he had around him. Though we had no native artists of note, such a large assemblage of foreign artists at the Courts of Charles II. and following monarchs could not fail to establish a foundation of knowledge which afterwards led to the foundation of a National School of Art. It was not, however, until the middle of the 18th century that the native revival showed signs of development into the modern English school. But from this time onwards we have such names as Hogarth, Reynolds, West, Gainsborough, and others too numerous to even mention in detail. Hogarth was practically the father of the English Modern School. His paintings, which were quite of a different type from any before his time, caused great enthusiasm by their humorous subjects. His works were principally satires on the vices and follies of his day. His success was not acquired without hard work and a great amount of perseverance. Sir Joshua Reynolds was contemporary with Hogarth and became the first President of the Royal Academy. His chief pictures are portraits. He attained some distinction as a writer by the publication of his famous discourses. Sir Benjamin West was born in America, and succeeded Reynolds as President of the Royal Academy. His works are not now considered of a high order, and he is chiefly celebrated for his having instituted a remarkable reform in the customs of art. Up to his time, when representing historical subjects it was considered the correct thing to represent all the figures in classical costume. In his picture of the Death of General Wolfe, he insisted on painting the soldiers and others in the exact costume of the time of the event, in spite of the objections of Reynolds and other members of the Academy. No one now thinks of representing this class of subject otherwise than in their natural dress; but nevertheless it was a bold step of West's to run counter to the rules and customs of the Academy at this time. Reynolds afterwards withdrew his objection, and the reform became a permanent one. Gainsborough was also a contemporary of Hogarth. His *Blue Boy* was noteworthy as being painted expressly to prove the falsity of a rule laid down by Sir J. Reynolds that no picture could be satisfactory in which blue or any of the primaries was the prevailing tint, and without question he succeeded in doing so, but it required a perfect master of the art to do it. The works of Wilkie, Constable, Turner, Landseer, Rossetti, and the Pre-Raphaelites, and a host of others would prove most conclusively (if proof were wanting) the existence of a purely British school of modern art. Nearly all these artists' works can be studied in our own National

Gallery or at South Kensington. Having sketched the origin of the Royal Academy, Mr. Fisher added: It is not generally known that the so-called Royal Academy is practically a private society. Though looked upon by the public as the "head of the art world," its influence on modern art has not always been beneficial; the placing a limit on the number of R.A.'s or A.R.A.'s is an absurd rule, and originated in the desire to exclude certain artists on its formation. The institutions for the teaching of art at the present time are—(1) the Academy, chiefly for those intending to take up pictorial art professionally; (2) the South Kensington Schools and Classes, principally (but not solely) for training in design and industrial art; (3) artists' studios and private schools for those principally taking it up as an accomplishment only. These are not strictly limited to the sections named, and many schools combine all three sections in their teaching. It, however, gives the general character of the work in each institution or school. Admission to the Academy schools is free to those passing the required test, and from 200 to 300 students may be seen daily at work there. The student who wishes to enter the schools as a painter must submit, at a stated time of the year, a chalk drawing of an antique figure not less than 2ft. in height. For those who enter as sculptors, a model of some well-known statue must be submitted. If these works are considered satisfactory, the student is admitted as probationer for three months, during which time he must make a similar drawing or model from a different figure as proof that the work sent was really his, and, in addition, some anatomical studies. If these are passed the student is then admitted for three years. It often happens that a student has to try many times before admission is gained. The course of study there is well known, and is very thorough. The South Kensington system is taught under three heads—viz.: (1) in the elementary or Board schools for very young children; (2) in the art night classes for elementary work, though a little advance upon the Board schools; (3) in the schools of art, in which all the higher branches are taught. Little need be said here of the instruction as carried on in the first two of these sections; but "schools of art" are at the present time suffering from the rivalry of so-called "technical schools," which are supposed (but erroneously I think) to be more practical than schools of art. No doubt the latter have (and do still in some parts of the country) given cause for being considered merely as places where young ladies and gentlemen pass a number of hours daily, in learning fancy drawing or painting, sufficient to enable them to pose as artists before their admiring friends and relatives, but serving no useful purpose, nor giving any practical instruction. This has created a certain amount of distrust among many, who have looked upon these schools as being intended for the upper and not for the lower classes. But this has been remedied in most places. As a system for the training of art workmen, there is none better than the S.K. system now if properly carried out. On the other hand, the opposite charge is often made against it—i.e., "that it is too mechanical." Nothing could be further from the truth. These objections are generally made by people who are too indolent to inquire into the matter. Nevertheless, there are many reforms still necessary, and not the least is the extravagant cost of the administration—it has been calculated that out of every pound granted by Government for art education, 15s. is spent on its administration—and a few of the sinecures there ought to be abolished. Another drawback is the fact that the control of the "Art Section" is practically in the hands of those whose sympathies appear to be with science only, and for some years the teaching of art has been much discouraged, while on the other hand science has been much favoured in many ways by the Department. Having briefly reviewed our art as it was, and as it is, a few remarks may now be given on what it should be. It ought to be more a part of our national existence—it ought to penetrate into every branch of industry—to enter more into the decoration of our houses, churches, and public buildings. Training in art ought to be more thorough, and form a greater portion of our children's education, to the exclusion of other useless subjects. With respect to purely pictorial art, there is not so much a lack of earnest work, but there ought to be less of that

disposition among artists to represent modern subjects as if we lived in the Middle Ages. Modern subjects in strictly modern costumes ought to be more represented in our public buildings; and it should not be forgotten that we live in an age of steam and electricity. To make my meaning more clear, let me refer you to what has been rightly considered among the greatest works of recent times—viz., the two frescoes at South Kensington Museum, by Sir Frederic Leighton. "The Industrial Arts of War and Peace." From a purely art point of view, they are almost perfection. And would it not have been preferable to treat these subjects according to modern ideas of peace and war? Would not the representation of casting modern heavy guns and other implements of war, and also modern occupations of peace, have been far better for the information of future generations? Surely the genius of Leighton or other artists is equal to the task of rendering modern costumes in a manner suitable for pictorial representation? Why should modern dress be so much objected to? As a matter of personal convenience (the ridiculous top hat excepted) it is far in advance of the Middle Age costume. I am disposed to think that Raphael, Michael Angelo, and the earlier geniuses would have been able to deal with modern costume just as well as with that of their own times. This tendency to old ideas may be observed in many ways, and we are still a little touched with the weaknesses of the times previous to West's days. Sculpture ought to be more encouraged, especially in connection with our public buildings. It is notorious that this branch of art has been seriously neglected. As it is always better to be able to point to definite examples than simply giving vague generalities, I would refer to examples of a good application of this branch, such as are worthy of imitation. 1st. With respect to detached or independent groups of sculpture, the Jubilee Memorial at Winchester, by Mr. Gilbert, A.R.A., is among the best, and if all our Jubilee memorials were like this one, we should have less regret at the waste of money expended on this commemoration. 2nd. As part of and dependent entirely upon architecture. Model in low relief by one of our greatest rising men, Mr. Geo. Tinworth, employed by Messrs. Doulton and Son. This is the work of a man who boasts that his whole education (apart from his art education), only cost the small sum of 2s. He is a remarkable example of what may be done by earnest work and perseverance. 3rd. As a combination of these two requirements—viz., a work which may be said to be independent of architecture to some extent, but yet depending upon it for its proper effect, we may specify the Paris Exhibition Group of the Fountain of Progress. This example may not be in the best taste, but it is remarkable for its life and vigour. Considering that it was all designed and executed in the short space of eighteen months, there is ample allowance to be made for its minor defects. It would be impossible to find a British sculptor who would undertake a commission of this nature in so short a time. And now, in conclusion, you have seen that in early times we had a national style; that from various causes it became extinct in the Middle Ages: and that without considering water-colour art, we have certain modern features, which though not perhaps amounting to a distinct style, are certainly peculiar to ourselves, and which, if carefully developed, will make their mark in future ages. I would make an appeal for a more extensive application of art culture in our general education. It is still too much a common superstition that art power is an inborn faculty possessed only by a few. It cannot be too widely known that all ordinary intellects possess these powers more or less, and which can be developed by perseverance and training. Art is useful in every position of life, absolutely necessary in many occupations, it has a softening and refining influence on the mind and manners, and tends to elevate the character, necessitates accurate observation, and brings into life and activity those faculties which might otherwise have lain dormant for ever.

Mr. H. ROUMIEU GOUGH, Past President, proposed a vote of thanks, and said he wished the lecturer had dealt more largely with architecture. People were too much inclined to look upon painting and sculpture as including all "art," and did not sufficiently realise its relationship to everyday life. He was sorry to hear Mr. Fisher condemn the establishment of technical schools as a mistake, for he believed they would do

great good to the English workman. The lecturer had advocated the introduction of modern costume into pictures; but our dress was so hideous that artists rightly declined to reproduce it. Still, an improvement was being made in this respect if we compared Leech's Sketches in *Punch*, and even Frith's "Derby Day" and "Margate Sands," with the garments now worn both by men and women.

Mr. W. H. SETH-SMITH, Ex-president, seconded the motion, and observed that when travelling in Norway last summer he was impressed by the resemblance of Scandinavian art to our Runic crosses and Early manuscripts. He believed there might be some basis for Du Chaillu's recently propounded theory of our Viking origin. The subject was most useful to architects, for the more they studied the sister arts the better would their work become. It was desirable that the general public should be interested in what was good and what bad in architecture as in the intelligent appreciation of its principles lay the chief hope for the future improvement of the art.

Mr. H. D. HATFIELD defended the examination system as applied to schools of art, remarking that the prospect of a test tended to impel the student to strive to reach a certain standard; the evil was that he too often made this passing an examination the goal of his ambition, and not merely a means of ascertaining how far he had advanced.

The PRESIDENT said as architects they ought to provide spaces in houses for pictures and sculpture to fit into; the modern gold frames were most inartistic, and he often felt a desire when going through a gallery to prune them down with an adze. He fancied Mr. Gough had misunderstood Mr. Fisher's criticisms of technical schools; the lecturer did not object to technical teaching, but thought it was unwise and unfair to add to those schools an art branch which competed on the same lines with the older schools of art. The practical question was how were we to imbue the minds of the young with a love of and desire for art? It could only be done by beginning in the elementary schools. If we compared the costume of both sexes and the home surroundings of the people of the present day with those of a generation since, we must admit there had been a great improvement.

Mr. FISHER, in reply to the vote of thanks, said the President had accurately stated his views as to the art departments of technical schools, which he held competed unfairly with the art schools already established at a great cost. Modern dress was the most convenient yet worn, and was certainly an improvement upon that of the last generation, with the exception of the tall hat. Examinations were, as Mr. Hatfield said, an incentive to lazy students to work; but they did not need to make all the machinery to fit the lazy student's case. There was, however, no other way of testing qualification than examinations. He believed that we had made great strides in art of late years.

#### THE CASTELLATED AND DOMESTIC ARCHITECTURE OF SCOTLAND.\*

THE third volume of the interesting and exhaustive work by Mr. David MacGibbon and Mr. Thomas Ross is before the public, and fully bears out the programme which the authors laid before their readers. We reviewed the first volume in our issue of Dec. 24, 1886, and the second in the *Building News* for April 15, 1887, giving specimen illustrations in each instance. The volume now to hand contains a further description of the architecture of the castles and houses from the 12th to the 18th centuries, and enters into a general survey of the subject and its bearing on social, historical, and artistic questions. The simpler keeps and castles of the L type of plan, embracing a part of the fourth period, is entered upon. In the introduction the authors trace in the architecture a record of the national development of Scotland; the successive types of castles and domestic buildings illustrate the progress from primitive conditions of life to those of refinement, the state of various classes of society. The prehistoric fortresses or "brochs" are in themselves especially interesting features of the country north of the Tweed—a product of Celtic civilisation belonging to a period previous to the

\* The Castellated and Domestic Architecture of Scotland from the 12th to the 18th Centuries. By DAVID MACGIBBON and THOMAS ROSS, Architects. Vol. III. Edinburgh: David Douglass.

11th century. In the later 14th century keeps, we find features which were undoubtedly borrowed from those of the brochs, especially the narrow loop openings, the galleries in the thickness of the walls, and a central courtyard. The Norman keep was generally oblong and of three stories, but was chiefly erected in Normandy and England, scarcely any being found in Scotland. Here, indeed, we find the old wooden fort upon its "motte" surrounded by an earthen palisaded mound or wall, as the Pele on Deeside, where Macbeth was slain in 1057. But after the Norman Conquest the Southern refugees introduced the English or Norman castle into Scotland, and this kind of building rapidly spread in the 13th century, and regular stone masonry began to be substituted for the earthen and wooden structures. The establishment of monasteries encouraged better building, and during David's I. reign and his successor the monasteries and churches of Kelso, Dryburgh, Jedburgh, Melrose, Holyrood, Dumblane, Dunfermline, Elgin, &c., were founded. Castle building followed, and of examples Messrs. MacGibbon and Ross have given several in their first volume. A great wall of enceinte, with towers and a keep, were the main features of these fortresses; stone and mortar masonry characterise these castles. In the 14th century the Norman keep was introduced, and its main features were preserved, the vaulted basement for stores, a common hall where retainers and guests fed and slept, and a third story for the lord and family. There were no bedrooms and no kitchen, the cooking being done at the hall fire. Ornamental features were absent on the 14th-century keeps, the corbeling being of the plainest kind, and angle bartizans corbelled out are the main points of interest. The masses were severe and rectangular, and the castles of this second period compare badly with the grander buildings of the first period, and indicate the influence of the wars of secession and independence. These protracted wars and internal strife impoverished the country, while in England large castles were being built, and considerable progress had been made in the plan and conveniences of habitations. In both France and England the decorative features were developed, and the castle became not only a fortress, but a palace. The 15th century saw an improvement: the Scotch plan was enlarged by the addition of a wing or tower at one end, and we have thence the L-shaped plan; the courtyard was introduced, and several illustrations show the result of this gradual accretion necessitated by the want of sleeping-rooms and kitchens, the latter often added to the wing, as at Borthwick and Elphinstone, and the corbellings were made ornamental; mouldings surrounded the doorways, which were placed on the ground level. The 15th century saw a further development of plan. Several halls and apartments were clustered round a central court, which thus became a feature, as at Tanbhallon and Dirleton, at Linlithgow and Stirling. The third period architecture (1400–1542) coincides with the Jameses, and several interesting plans and sketches are given. The first is Castle Stalcaire, Argyllshire, standing on a sea-girt rock. The keep is rectangular, 50ft. by 40ft., and four stories high, entered on the first-floor level. Kinlochaline, Craignish, Fairlie Skelmorlie are castles of this type. Carrick Kames, Saddell, Sorn, Mains, and Ackergill castles are among other structures described and illustrated. The L-shaped plan is well shown by Lethington Castle, Haddingtonshire, of which the plans of each floor is given; it is of the 15th century. The keep of Hatton House, Midlothian, is also L-shaped, the mansion being built round it. Other examples are Bridge Castle, Linlithgowshire, Stanely, Renfrewshire; Dalzell Castle, Lanarkshire; Craige Castle, Ayrshire; though some of these are of a mixed character, are of three periods, and illustrate the courtyard arrangement. Various special plans are shown, including the fine castle of Dalquharran, Ayrshire. In the fourth period (1542–1700), the latest development of castellated architecture, the plans became more elaborate, and partook the shapes of the letters Z, T, and E, though the L-form and the simple keep are noticed still. Of this period mention is made of Busbie—a simple keep; Newark, Hills, Oakwood Tower, Sellarkshire; Minto Tower, Roxburghshire; Invermark Castle, Forfarshire; Castle Craig, Ross-shire; Bedlay House, Lanarkshire; Monkland House; Higgs Castle, Renfrewshire, having some good details and corbeling; Dundarave Castle, May-

bole Castle, Ayrshire, amongst others, in all of which the progress towards refinement and domestic conveniences is evident. Messrs. MacGibbon and Ross's new volume is an important addition, and forms, with the previous volumes, a valuable contribution to the history and progress of Scottish architecture. A fourth volume will contain the remaining edifices of this period, and will include illustrations of houses and mansions from several towns.

#### SECULAR ARCHITECTURE.

THE first of a series of three lectures, arranged by the Free Libraries Committee of the Manchester Corporation, was delivered by Mr. Alfred Darbyshire, F.R.I.B.A., in the Free Reference Library, King-street, Manchester, the subject being "Secular Architecture." Having described the civic and domestic architecture of the ancients, the lecturer turned to the consideration of modern secular architecture, asking what were the aims and objects of architectural art? There was a wide difference between architecture and building. The latter was a mere piling up of material to secure a shelter or to inclose a space, and comprised constructive device or engineering skill, while the former was an art which made the construction beautiful and rendered artistic what would otherwise be only utilitarian and prosaic. He claimed for architecture that it was the groundwork on which the sister arts of painting and sculpture were displayed, and on which they found a fitting medium of expression. If this was a true position for architecture to assume, it was evident that the art had a high responsibility, and unless we had good architecture it was useless to expect a perfect work of art. In considering modern secular architecture it would not be necessary to notice buildings which were of a purely utilitarian character, such as cotton mills, &c., or houses which had merely openings for doorways or square holes left for light to enter. He was sorry to have to confess that English towns had been planned without any regard to a grand architectural result, and in this respect we were far behind our Continental neighbours. As the buildings in which merchandise was produced were as a rule only utilitarian in character, and had little or no expression architecturally in brick and mortar, he would consider the warehouses or buildings in which the manufactured article was exposed for sale, or from whence it was shipped. If there was one thing in Manchester which had rendered the city famous in modern history, it was the palatial warehouse architecture of its streets. There was no city in the kingdom which could show such a complete architectural epoch in commercial architecture, and although the great genius which brought it into being had passed away, Edward Walters had left his mark upon his day and generation in the warehouse architecture of Manchester. Railway stations, next to shops, were surely the most unfortunate media of architectural expression. There was certainly some true architectural pretension at London-road Station in Manchester, but taking the three commanding sites of London-road, the Midland, and the Exchange Stations into consideration, was there ever such a grand opportunity lost for the massing of architectural form and for the realisation of a grand skyline? The town halls of the Mediaeval and Renaissance ages might be ranked amongst the finest buildings which the art of architecture had given to the world. During the last half-century the towns and cities of this country had vied with each other in the erection of municipal monuments of architecture, and he need only remind them of the grand examples which might be found in Birmingham, Leeds, Liverpool, Bradford, Bolton, and Manchester. Some of the examples of town halls were conceived in the spirit of our national Gothic architecture, and their own city hall might be taken as one of the latest expositions of its adaptability; but we were yet wanting a style of architecture which should fully reflect the light of 19th-century civilisation and advancement. In the theatres of the future the initial condition should be that such buildings should stand completely isolated from other property. The stage should be capable of being instantly isolated from the auditorium by the closing of the proscenium opening, and the highest point accessible by an audience should be as near to the streets as possible, while no seat should be higher than the proscenium open-

ing. Every part of the house should also be provided with two exits; the stage should have a fireproof roof with a smoke-shaft glazed and louvered, and every space upon which the human foot was planted in the auditorium and escape staircases should be absolutely fireproof and unburnable. He had been told that it was impossible to carry out these conditions; but to that he replied that they had now become actual facts. In the great theatre now being erected in Manchester the promoters had determined that it should be a safe theatre and a faithful realisation of the principles of theatre architecture. In a few concluding words on the present position of secular architecture, Mr. Darbyshire said our own time had produced some curious changes in architectural style and construction. In a state of civilisation such as this it was almost useless to speculate on the future of English architecture. The age must have time to cool down; men must pause, and, like the grand old Greeks, must begin to love the beautiful as well as the useful. The filth and dirt of manufacture must be reduced and regulated rigidly by the State, so that we might give life and beauty to our secular architecture by the charm of colour under the clear light of heaven. Men must learn that the beautiful could be made as cheap as the useful, and ugliness must be banished from our streets; then, and then only, could we hope to reach a "Golden Age," in which our national architecture should develop new forms and fresh beauties, and when our architects should have honour and respect, and leave behind them "footprints on the sands of time."

#### INSERTION OF BEAMS IN WALLS AND OTHER CONNECTIONS.

IN the instances of disastrous fires, both in this country and America, we have abundant proof of the danger attending the fall of outer and internal walls. Mr. Harry A. Goetz, in a paper read before the National Association of Fire Engineers at Kansas City, calls attention to the value of a brick wall as the most formidable barrier to the spread of flames, which no one can dispute who is aware of the danger of walls collapsing during a fire. He alludes especially to the causes of the failure of walls during fires, one of which is the imperfect methods of anchoring, or the methods by which beams are secured to the walls of a building. Mr. Goetz says architects, builders, and inspectors neglect this important security. Generally the joists are cut on a splay of about 3in. to the foot at the ends, this splaying being done to permit the joists to fall out without damage to the wall. This advantage is generally counteracted by the mode of fastening the tie to the joist and wall, so that when the joist drops, its weight acts as a lever to tear the wall or cause it to topple over, through the tie being passed through the wall and screwed up on the outside. Sometimes the tie does not go right through the wall, but only reaches to the back of facing, so that when the joist falls out the tie drags away the inside bricks which secure the end of the tie to the wall, and which will have a tendency to fall inwards in consequence. After showing a number of the forms of tie used, which consist merely of a bar or strap of iron fixed and bolted to the top or side of joist, and projecting so as to go through the wall with turn-up-and-down ends or cross pieces of iron, the author draws attention to a method of anchoring which obviates the objection to this system of fastening, which consists of a cast-iron box of dovetail shape, whereby it is locked into the wall into which it is built, and on the seat of the box is a projecting lug, over which the joist is notched. This socket or box may be plain, consisting of an oblong box, but without one side, and a top into which the end of joist is inserted, cast dovetail shape on plan, with a lug as described at the bottom. Another form shows side guides with perforations or slots, which allow a circulation of air round the end of joist. The falling joist frees its anchorage, but without pulling the wall, while the weight on joist, when in the wall, increases its stability. The box is fire-proof, and can be inserted near fire flues without danger of ignition of the joist. For heavy beams the bottom of the box is made to extend and form flange-like projections, giving a wide bed-plate, which flanges, having the weight of brickwork on them, secure the box or socket. The same method can be applied to a party or partition wall, the boxes being built in

on each side of wall to take the opposite joists. If one floor is destroyed, that on the other side of wall is unimpaired, and there is no risk of the burnt out ends causing wall to topple over, as the iron boxes still remain embedded in the wall. By this plan the ends of opposite joists cannot touch and cause the fire to pass through the wall as it often does.

Another cause of speedy destruction during a fire is the manner wooden posts or pillars are made to carry others above them, when one of the horizontal beams, which are generally introduced between the head of one post and the bottom of the other, falls and destroys the footing of the upper post. Several methods of connection are shown; the author's improvement consists of fitting a cast-iron cap on the lower post with extended flanges or brackets to carry the side horizontal beams which are notched on lugs cast on the extending cap; there is also a socket formed to let the foot of the upper post into. The posts rest end to end with no shrinking or crushing timber intervening. The cap and posts are securely bolted together, while the horizontal timbers can fall away without pulling or injuring the remaining parts. The casting is bolted to the bottom of upper column, which holds the whole up if the lower post should be burned away. Mr. Goetz's method is certainly a good one, and deserves the attention of architects.

#### BRICKS AND BRICKMAKING MACHINERY.

By M. POWIS BALE, M.Inst.M.E.; A.M.Inst.C.E.  
Author of "Woodworking Machinery," "A Handbook for Steam Users," &c.

#### PLANT FOR PREPARING CLAY FOR THE PLASTIC PROCESS.

ALTHOUGH the effect of "weathering" the clay before it is made into bricks varies largely with the nature of the clay, it is a process very generally pursued. The clay is dug in the autumn, and left in heaps near the machines—such as pug or wash mills—that are afterwards used in preparing it for moulding. The object, of course, is that the clay may be mellowed and softened as much as possible by the atmosphere and frost of winter, so as to render it more readily dealt with when brickmaking commences in the spring. The clay should, therefore, be left exposed as much as possible to the weather, and some makers go to the expense of having it watered and turned during the winter. In the London district, where it is necessary to mix breeze, chalk, &c., with the clay, and in many cases to wash it for clamp burning, it is dug and mixed with the sifted breeze or coal ashes in proportion to the nature of the clay, chalk being usually added to improve the colour and assist in binding the bricks. We have also seen clay prepared and covered with breeze in layers in the proportion of about 2in. of breeze to 1ft. of clay, the breeze and clay being afterwards thoroughly mixed. In the manufacture of London stocks of superior quality wash and chalk mixing mills are largely employed; the clay in the first instance is washed in the wash mill to remove stones and impurities, till it is reduced to "slurry"—a thin paste. Chalk in a similar condition is then mixed with it, either in the wash mill or in a mixing mill especially designed for the purpose. The slurry is then either pumped or run by gravity into pits or "washbacks," where the excess of water is drawn off and evaporates, leaving the clay sufficiently dry to be used for brickmaking in the spring. With the ordinary clay found in the Midlands and North of England, the best plan for weathering, and the one usually pursued, is to cut the clay in as thin layers as possible—say about 1in. thick—and forming heaps as lightly as may be, water being thrown on the clay about every 2ft. of thickness, the quantity of water used, of course, being regulated by the nature of the clay. This method of watering will render the clay of more even consistency than if the water is thrown on the top of the heap only. To prevent the clay becoming too much dried up, its surface should be covered with a layer of sand. It need hardly be said that the thorough mellowing of the clay by weathering expedites the after processes, and improves considerably the quality and quantity of the output. In the case of strong clays, street sweepings or sand are often added, the whole being covered with a layer of fine ashes.

Fig. 3.

## CHAIN GEAR WINDLASSES, HOISTING GEAR, AND ELEVATORS.

Although shafting and belt pulleys have been introduced into a few London fields, windlass chain gearing is still chiefly employed for driving pug mills, wash mills, &c. An additional advantage arises from the use of this gear in cases where the beds of clay are thin, as the pug mills can be moved from place to place as required, the driving chains being lengthened to suit.

As will be seen from our illustration, Fig. 3, which is from the designs of Messrs. Bastin and Lawson, London, the windlass consists briefly of grooved wheels or drums mounted on a shaft running in bearings in a suitable frame, and actuated by a crown wheel and pinion. It is fitted with a second motive shaft for driving washing or pug mills, as may be required, the former being used in winter in preparing the clay, and the latter in the brickmaking season.

As this machine is subject to very considerable strain, it should be of massive construction, and mounted on a good foundation. The bearings should be of ample area, and capable of adjustment for wear. It is a good plan to pass the foundation bolts entirely through the brickwork.

As in many brickfields clay has often to be raised a considerable depth from the clay-holes, &c., to the crushing rolls or pug mills, various kinds of hoists and elevators have come into use. For hoisting the clay from the clay-pit a chain-winding gear, either separate or combined with the crushing rolls, is usually employed in conjunction with a clay truck running on rails down an incline into the pit. This hoist should in all cases be powerfully geared and fitted with a brake to regulate the speed and clutch or other arrangement to instantly throw the hoist in and out of gear. In the London district, for raising the washed earth or chalk, belt or chain elevators and conveyors are chiefly employed; but in some cases a wheel elevator is to be preferred. The belt elevators consist briefly of a series of hoppers or buckets mounted on an endless belt or chain arranged to run round the pulleys or drums placed at the top and bottom of the elevators. These pulleys are mounted on spindles running in gun-metal bearings, and are put in motion through the medium of belt, spur, or chain gearing.

## WASH AND CHALK MILLS.

As we have elsewhere remarked, the only really effectual way to get rid of the small lime-stones, &c., found in most samples of the London clay is to wash it. Wash and chalk mills consist

briefly of circular pits or walls with brickwork or wrought-iron sides. In the centre of this is mounted a vertical shaft, driven by suitable gearing, and carrying a series of six to eight radiating iron arms, to which is given a rotary motion. From the arms are suspended by chains iron or steel tined harrows of considerable weight, with long tines; these just clear the bottom of the mill when empty. The mills can be driven by belts or chain, as may be most convenient. The clay is tipped into the mill and thoroughly washed, the stones sinking to the bottom of the mill, from which they are afterwards removed. The pump supplying the water is often driven by a crank from the bevel gear shaft working the mill. The chalk mills are usually made considerably smaller than the clay washing mills, and are placed near them, but on a little higher level, so that the prepared chalk will readily run into the clay mill. By the aid of the wash mill and a suitable admixture of chalk, breeze, &c., it has been proved possible to make almost any kind of clay into fairly serviceable bricks. It is important to successful working that the footstep bearing carrying the vertical shaft of these mills is carefully arranged, and especial means taken for lubrication, and some remarks will be found on these points elsewhere.

## CRUSHING ROLLS.

We may mention that in dealing with plastic or shaly and stony clays, marls, &c., to reduce them to a uniform condition, enabling them to be dealt with in the pug mill, it is often necessary to use crushing rollers. These consist briefly of one or two pairs of chilled iron rollers, strongly geared together by toothed gearing, mounted in a massive cast-iron frame, braced together, and driven usually by a belt. The rolls are fitted with scrapers, and generally thrown in and out of gear by means of a friction pinion and clutch, and the gearing, which is often severely strained, is fitted with self-acting friction belt to prevent breakage. The rollers are driven at different rates of speed, thus producing on the clay a rubbing as well as a crushing action. The four roller mills are used for any hard or difficult clays, the lower rollers being set closer together than the top, the clay being thus gradually reduced to the desired consistency. Occasionally, when very hard clays have to be reduced, the top rollers are "hedgehogged"—i.e., are cast with teeth or projections, which break the clay up before it passes downwards to the smooth rollers, which complete the process. The machine is fitted with a suitable hopper, and the clay is

usually well watered or soaked before being passed into the machine, but some marls are passed through dry.

Clay-crushing rollers are also made in segments and fitted, a square shaft thus enabling the centre parts of the roller to be moved to the ends as they become worn. It is claimed for this arrangement that it combines the advantages of "hedgehog" and smooth rollers, and will readily grip any class of clay with the minimum amount of labour in feeding.

We have seen doing very excellent work a combination of smooth, tapering crushing rollers running at different speeds in conjunction with an adjustable transverse roll of irregular form fitted with long teeth, which break up the clay and separate the large stones. In clays containing stones, to make satisfactory material it will be necessary to screen all the large stones, and the small ones should be crushed so fine as to not show in or damage the brick when burnt. In America some machines are made with the crushing rollers placed inside a pug mill. We fail to see, however, what advantages can be claimed for this arrangement, as it certainly complicates matters, and renders adjustments and repairs more difficult.

## PUG MILLS.

A very important operation in the preparation of the clay before being dealt with by the moulding machine is pugging—that is, the thorough mixing of the clay, so as to render it perfectly homogeneous and uniform in its nature. If this is not properly and thoroughly done, the result is unsatisfactory, whether the manufacture be bricks, tiles, or pottery. Pugging, or tempering, was formerly done to a considerable extent by hand labour, but has now—except in very small fields—given place to the pug mill. This consists briefly of a large iron or wooden vertical or horizontal cylinder, in which is mounted a shaft or shafts carrying a series of knives or blades, mounted after the fashion of a screw. The clay being thrown into the top is cut and mixed by the knives, and passes out through a shoot in the bottom of the cylinder, and is then conveyed to the moulding machine. The mills can be driven by belt, rope, chain, or other gearing, or horse-power. Pug mills, both vertical and horizontal, are often combined with the moulding machine as one machine. For separate use, vertical iron mills are generally to be preferred, and care should be taken that the footstep bearing occupying the vertical shaft can be readily lubricated, and is adjustable for

FIG. 4.

wear, or it may give considerable trouble and consume unnecessary power in driving. The mill should be mounted on an extended bed-plate to secure strength and rigidity in working; it can be driven either from above or below. For large mills the latter arrangement is perhaps to be preferred, as being steadier in work. The details should be so arranged that the knives can be readily adjusted or the shaft drawn if required. Some manufacturers make the top of the cylinder bell-mouthed, so as to facilitate the feeding of the clay. Scrapers for keeping the surface of the mill clear and preventing the clogging of the clay should be fitted, as it is amalgamated better, and the driving power reduced. The knives may be of steel, wrought or hard cast iron, the first for preference. In the case of uneven and refractory clays, a mixing-pan is sometimes combined with the pug mill; this is usually placed in the top of the mill, and consists briefly of a cast-iron pan, in which four adjustable arms are made to rotate horizontally. The clay, mixed with water, is placed in the pan, and after being well mixed is passed on into the pug mill.

Our illustration, Fig. 4, represents a pug mill, from the designs of Messrs. Clayton, Howlett, and Venables, of Harrow-road, London. As will be seen from the illustration, it is mounted on a timber and brick foundation, and driven from below by a belt. The cylinder is made with two outlets for the clay, and with a door to admit of cleaning the knives. Sluices can also be fitted for regulating the delivery and consistency of the clay, if desired. The knives are arranged on the principle of the Archimedean screw, so as to both cut and turn the clay over at each revolution. Scrapers for cleaning the sides of the mill and preventing the clay clogging are also fitted. The mill can be arranged to drive from above by means of chain gearing, if desired. The horizontal form of pug mill can be readily mounted on wheels when it has to be conveyed from place to place for temporary contract work. For transport in difficult countries on mule back, &c., pug mills can be readily made in sections, and put together at the place of destination. A convenient way is to make them of boiler plates, with strong angle-iron framing. Amongst hand moulders there is, however, a prejudice in favour

of vertical pug mills, in preference to horizontals. Tempering wheels are sometimes used instead of pug mills. These consist briefly of a large skeleton wheel, which is made to travel round a mud "race" or pit by the aid of suitable gearing. Pug mills fitted with two shafts and mixing screws running at different speeds have been introduced with success, and it is claimed for this arrangement that it will turn out a larger amount of clay, and that it is more thoroughly homogeneous than is the case with a single screw, and when it is combined with a brick-moulding machine the pug mill can be reduced in length.

#### PUMPS FOR BRICKFIELDS.

Single, double, or treble-barrel pumps mounted on frame, with crankshaft, and fast-and-loose pulleys or toothed gearing—or in lieu of gearing, chain-wheels—are largely employed for pumping slurry, &c., in the London fields. A large single-barrel pump is to be preferred to a smaller double, as there is less liability to stoppage from the valves becoming choked. Whether a single, double, or treble pump be used, a door should in all cases be fitted to each valve to allow of the ready removal of any obstruction. A long-stroke pump is to be preferred for this duty, as it is important the liquid should have as few reversals of its flow as possible, and there should be no complications in the passages or corners where the mud can readily accumulate. The valves should be as large and free as possible—gunmetal clack valves are suitable. Occasionally it has been found convenient to pump the slurry a mile or more through pipes; in this case the strength of the pump must be increased. Centrifugal, rotary, and chain pumps are often found very useful for brickyard purposes where the lifts are low, and they all possess the additional advantage of being without valves and packing, and cannot well be damaged by frost.

A requisition signed by the Mayor of Plymouth and a number of leading citizens and plumbers has just been received by the Plumbers' Company, desiring that a centre should be established at Plymouth to carry out in South Devon the Company's system for the technical education and registration of qualified plumbers.

#### COMPETITIONS.

**ISLE OF MAN.**—At the last meeting of the Braddon School Board, plans submitted in open competition by Mr. Thomas W. Cubbon, architect, of Birkenhead, were unanimously adopted for new school buildings about to be erected at Kemaigine.

**LEEDS.**—As the result of a competition, designs submitted by Mr. William H. Thorp, architect, of 61, Albion-street, Leeds, have been selected for a new synagogue, to be erected on a site having frontages to Merriion-street and St. John's-place, in that town. The new building, which will supersede the existing premises, now inadequate for their purpose, is designed to accommodate 1,000 worshippers. The synagogue will be a large rectangular-shaped room, 67ft. 6in. by 55ft., having on three sides galleries reserved for the women; accommodation for the men being provided on the ground floor. In the centre will be a raised platform, for the use of the reader and choir; and at the eastern end, situated on a raised dais, will be the "Holy Ark," placed within an arched recess. In the basement there will be a schoolroom, and rooms for the use of the caretaker. The building is designed in an Oriental style of a Saracenic type, and will be in brickwork, relieved with stone dressings.

**NEW CONSERVATIVE CLUB FOR OSWALDTWISTLE.**—The present premises of the Oswaldtwistle Conservative Club have been found totally inadequate to accommodate the members, and it has been decided to build a new club. At a meeting last week, out of a number of plans that of Mr. Shorrocks, of Simmons-street, Blackburn, was selected. On the ground-floor of the adopted plan there is an assembly room, 50ft. by 26ft., provided for, capable of holding about 300 people; a reading-room, 17ft. by 25ft.; a committee room, and secretary's room. There is also the hallkeeper's dwelling, consisting of house and scullery. On the second floor there is a billiard-room, 50ft. by 27ft.; card and smoke rooms, a bar, and accommodation for the hallkeeper. There is nothing ornate about it; but it appears a good, substantial building, and the internal arrangements are well adapted for club purposes. The proposed cost is £1,000.

## OUR LITHOGRAPHIC ILLUSTRATIONS.

## CONTEMPORARY BRITISH ARCHITECTS.

For description see p. 115.

CHURCH OF ST. MARY MAGDALENE, WORCESTER.—NEW TOWER AND SPIRE.

The church was erected in 1876, under the superintendence of Mr. Preedy, from designs prepared with the assistance of Mr. J. S. Alder, of Palmers-ton-buildings, Old Broad-street, London, E.C., the architect of the tower and spire now completed. The tower measures 21ft. square at the ground, with double buttresses at each angle in addition, and rises to a height of 80ft. The spire is 20ft. in diameter at the bases, and rises to a height of 110ft. 3in., thus making a total height of 190ft. 3in. from the ground. Provision has been made for a peal of eight bells. The upper portion of the tower, as well as the whole of spire and pinnacles, is built in best Portland cement. The tower facing is of Bromsgrove sandstone, and the dressings of windows, entrances, buttresses, &c., and the spire walls and pinnacles are of selected Westwood Ground Bath stone. About 12,000 cubic feet of stone have been used. The builder is Mr. Albert Estcourt, of Gloucester. The carving was done by Mr. Martyn, of Cheltenham. The dedication services were held on Sunday, the 22nd Sept. last, by the Bishop of Worcester. The five-light east window of chancel has just been filled with stained glass. The tower and spire and the new window are intended as a memorial to the late Colonel Johnstone, who contributed generously to the funds for the erection of the church.

## THE HOTEL METROPOLE, MONTE CARLO.

COMMENCED so recently as December, 1888, covering an area of ten thousand metres, and capable of entertaining at once some four hundred guests, this latest addition to the hotel accommodation of the Riviera was opened to visitors on November 26th last. The Hôtel Métropole, rising terrace by terrace from the main road, occupies a superb position—perhaps the finest in the Riviera—on the eminence between the Monte Carlo railway station and the Casino, and fortunately, by the company's acquisition of adjacent land, can never be overlooked, the east, south, and west sides commanding splendid views of the Mediterranean and its coast scenery. This is especially the case with the restaurant, a magnificent *salon*, in three divisions, about 140ft. in length, and also with the *table d'hôte* room beneath. On a level with the former, on the south side, there is an open arcade, forming an extension of the well-known Galerie Charles III., which will furnish the hotel guests with a delightful promenade, bringing into view the prominent Cap Martin, the romantic Roquebrun, and other picturesque objects, and almost immediately overlooking the Mediterranean. The architects have been Messrs. Giles, Gough, and Trollope, of London; M. Terslin, of Mentone, acting as assistant resident architect. M. Viu has been the contractor, executing his task with

exemplary rapidity; Mr. George Jennings has had charge of the sanitary arrangements, and the laying out of the gardens and grounds, which are divided from those of the Casino by some 20ft. only, has been intrusted to M. Keller, the Paxton of the Riviera. The building is constructed entirely of granite, iron, and concrete. The walling is wholly of granite, carried over openings on iron girders. The floors are throughout of concrete and iron, and the roof is a concrete flat. The floors in the rooms are covered with parquet, and in the passages with mosaic. The whole of the exterior is worked in cement stucco. When the method of construction is considered, it is more surprising that the building could have been completed in so short a space of time. Cranes and hoists are unknown, and each stone for the walling is carried up "on the back" into position, sometimes two or four men carrying one stone between them on a pole. Beyond the furniture, most of the internal fittings have been sent from England, Mr. James Hill, of 100a, Queen Victoria-street, having supplied all the locks, door, and window furniture, and fanlight openers—the locks being of a special pattern, with master-key and grand master-key arrangements throughout. Messrs. Waygood and Co. made all the lifts.

## ROYAL VICTORIA HOSPITAL, BOURNEMOUTH.

YESTERDAY, the 16th inst., this hospital, which was built to commemorate the Jubilee year of Queen Victoria's reign, was formally opened by H.R.H. the Prince of Wales. The hospital is divided into different wards, with accommodation for 25 beds; but the central administrative block is large enough to allow for the ultimate extension of the building for 50 beds. The basement has cellars and heating chamber. The plans illustrate how the accommodation on the ground and first floors, and the central block is carried up another story, containing kitchen, offices, and bedrooms for the hospital staff. The west wing of the ground floor is entirely occupied by an outside dispensing department. The walls are faced externally with Purbeck stone, Portland stone being used for the moulded work, quoins, and other dressings. The architects were Messrs. Creeke and Gifford, and the builders Messrs. George and Harding, both of Bournemouth. Mr. J. Halcrow was the clerk of the works.

## DETAILS OF OLD HOUSE, SOUTH QUAY, GREAT YARMOUTH.

WE have on former occasions given some of Mr. Charles J. Brooke's drawings of this house, showing other parts than those illustrated by the accompanying double-page plate to-day. We may refer to the previous illustrations, when particulars of this house and the Star Hotel were given—viz., BUILDING NEWS, April 30th and May 28th, 1886, for drawings of the Nelson Room at the "Star," and December 30th, 1887, for ceiling at South Quay, and March 30th, 1888, for sides of Great Room. The Queen's prize was awarded to Mr. Brooke for his set of plans, which comprised a complete monograph of this most interesting piece of work.

An action to recover £200 under the Employers' Liability Act was brought at the Wellington County Court, on Friday, by a labourer named Machin against Mr. C. R. Clark, contractor, of Stoke-on-Trent. Machin was at work upon a shed at the West Midland and Shropshire Agricultural Show when it collapsed, and he was thrown to the ground sustaining serious injuries. Machin stated that the ladder was too short, and that he called the foreman's attention to this, but was told to ascend. Had the ladder been of sufficient length there would not, he said, have been any necessity for him to get on the roof of the shed. The foreman and others denied that plaintiff made any complaint about the ladder. His Honour gave a verdict for the amount claimed.

The Godefroid de Bouillon Preceptory of Masonic Knights Templars, Stoke-on-Trent, having placed a statue of Godefroid de Bouillon in one of the niches on the south side of the Consistory Court of Lichfield Cathedral, a party of Knights, accompanied by their Provincial Prior, went to Lichfield on Wednesday week to formally make the presentation. The figure was executed by Mr. J. J. Millson, of Manchester, and represents the leader of the First Crusade in the act of starting forward and drawing his sword.

Mr. P. J. Sheldon, borough surveyor, of Burslem, has been appointed chief surveyor of main roads to the Essex County Council. There were 61 candidates for the post.

## THREE MEMORIAL CROSSES.

CHURCHYARD CROSS AND LICH GATE AT OGLE PYCHARD.

THE Cross and the octagonal steps upon which it stands are of Forest of Dean stone; the Lych-gate is of oak, roofed with oak shingles, the walls being of red and white stone from the Grinshill Quarries, near Shrewsbury. The work has been carried out by Mr. Robert Clarke, of Hereford. Mr. Bertram Heywood, B.A., is the architect.

## MEMORIAL CROSS AT PENARTH.

This monument was erected a short time since in memory of a well-known Cardiff architect, the late Mr. H. C. Harris, A.R.I.B.A. In accordance with his special wish, the cross was designed by Mr. Maurice B. Adams, F.R.I.B.A., and a Celtic treatment was adopted in obedience with instructions. The work was thoroughly well carved out in marble and stone. The carving was done by a local firm, from the architect's full sizes. An attempt was made on the part of the designer to give a contemporary character to the cross, and while adopting an early type of work, mere archaic details were avoided in the ornamentation. The main stem of the structure tapers in thickness, and the square bosses on the cross are cubes, with raised centres on the edge faces. The returns or edges are enriched to correspond with the front and back of the monument, both sides being ornamented. A curb incloses the grave.

## MONUMENT AT EXETER.

This Cross, of good proportions and simple design, was erected to the memory of more than 160 persons who perished in the disastrous fire at the Exeter Theatre—a catastrophe which is still fresh in the minds of most of us. The cross is in stone, the base being of granite. Mr. Harry Hems, of Exeter, was the sculptor.

## CHIPS.

A richly-carved Runic cross, executed in grey mountain limestone by Messrs. Farmer and Brindley, of Westminster, has been placed over the grave of the Rev. G. R. Portal, hon. canon of Winchester, in the churchyard at Burghclere.

New banking premises are about to be erected in Boscawen-street, Truro, on a site now occupied by a draper's, from plans by Mr. Silvanus Trevail, M.S.A., of that city.

The museum of Egyptian antiquities has been removed from Boulak to Ghizeh. The new building was opened by the Khedive on Sunday.

Mr. John Farnworth, timber merchant, of Liverpool, has bequeathed to charities in that city connected with the Wesleyan denomination £22,500.

The contract for the construction of the Glasgow Harbour tunnel at Finnieston, to provide for passenger and vehicular traffic between the opposite sides of the river at that point, has been given to Messrs. Hugh Kennedy and Sons, Partick, Glasgow. The undertaking will consist of three tunnels, two of which will be for vehicles and the third for passengers. Messrs. Wilson and Simpson, C.E., are the engineers of the tunnel.

At a general assembly of the Royal Institute of British Architects, held on Monday evening, the following were elected members:—A. E. Brockbank, Gordon Browne, Val. Davis, Charles H. M. Kerr, Davidson Knowles, F. H. A. Parker, J. L. Pickering, S. Sidley, and Arch. Webb.

At the meeting of the Bradford town council held on Tuesday a resolution was adopted authorising the expenditure of a sum not exceeding £10,000 required for electricity works; also another appointing Mr. Sydney Baynes as managing engineer of the electricity works at a salary of £250 per annum.

Mr. J. Dyer Edwards, formerly of Victoria, Australia, but now resident in England, has presented to the trustees of the Anglican Cathedral at Melbourne a very fine peal of bells. They have just been cast at the foundry of Mears and Stainbank, Whitechapel, London. The peal consists of 13 bells, a semi-tone being added to the proper peal of 12. The tenor bell, which is the largest, weighs 31½ cwt., and is 4ft. 8in. in diameter. The smallest bell of the peal weighs 5½ cwt.

Mr. Lees Knowles, M.P., secretary of the Guinness Trust, has invited the co-operation of the Dublin Corporation in selecting sites for building dwellings for the poor. Mr. Knowles also appeals to owners of ground in Dublin and others to aid the trustees, who are anxious to begin work in Dublin at once.

## WAYSIDE NOTES.

**TOWARDS** the close of last week I observed a statement in an evening paper to the effect that a very large number of competitors—somewhere about two hundred, if I remember rightly—are engaged in preparing designs for the proposed Watkin monstrosity or “Eiffel” tower. Considering the nature of the competition, it is a little surprising that so many are in the field. Had one-fourth of the individuals been at work on this mad scheme, it would have been a large number. What is scarcely less surprising is to learn that many of these competitors are of “great eminence.” One would have thought that these eminent gentlemen could have better employed their time. Unless something be produced so as altogether to out-Eiffel M. Eiffel himself, the author of any design that may be selected need hardly expect his name to become such a universally household word as that of the Parisian engineer. I don’t want to discourage, however; so those on the job please peg away. It is my hope that *all may win*.

The poor little King of Spain has been unwell, and it was urged by the Queen-Regent as a sign that His Majesty was progressing favourably, that “he asked for his box of building bricks, and commenced building an Eiffel tower.” When His Majesty is old enough to take the reins of the country in his own hands, there should be great attention paid to the development of architecture and engineering in the Peninsula, seeing that, at such a tender age, the king essayed to construct an Eiffel tower.

The Sheffield people are on the right track. They deserve the respect and regard of the architectural profession for the pains they are taking to render the competition a success. In dual competitions the essence of the thing is to keep it dark throughout, so that sweetness and light may be the ultimate result. The names of the successful competitors should be rigidly preserved; their several exhibits kept from the eyes of Paul Pry and his fellows; and no exhibition of unsuccessful drawings should be made until the premiated competitors have sent in their perfected schemes. There would appear to be some danger that this latter point may not be observed at Sheffield. An exhibition is proposed, and may be shortly holden. If so, it is a pity. Better by far wait till such time as the sketch designs of the successful men can be shown alongside. Otherwise the interest of the exhibition is marred: one cannot compare successful with unsuccessful, and young architects, who have tried their hands, have not such a chance of gaining experience from the process of comparing and examining.

I am not politician enough to say, off-hand, of what shade of politics is the town of Gainsborough, but it is not *liberal* in its attitude to architects. In the face of a decided improvement in competition inauguration, one might well afford to accost the Corporation of Gainsborough with, “Take it home!” and other derisive expletives of a kind generally employed by architects in polite society. The £5 premium is little better than an insult.

Of the many outward signs of the spirit of utilitarianism that is abroad at this day, perhaps none are more expressive than the fact of the frequent desire, on the part of those having authority, to make some practical use of ancient buildings other than show, and the entertainment of the eye of the ordinary sight-seer, as of the artist, architect, and archaeologist. The latest instance of this economical spirit is to be noticed in last week’s list of tenders, wherein it will be seen the Nottingham Corporation are about to convert a further portion of the so-called “Castle” buildings into an art gallery; as we all know, the main portion of this Italian mansion, erstwhile the seat of the head of the Pelham-Clintons, has for some years been restored to serve as a museum, and admirably does it serve its new purpose. This useful method of employing an old castle has been practised before, and in many instances the utilisation of an ancient building for some latter-day purpose means the salvation of its architectural features by timely repairs. Still, the conversion is to be taken as a true index of the utilitarian spirit of our own times. “The castle must not be a mere vanity,” thinks the town, “but must serve some practical purpose.” At Norwich the old keep has been con-

verted into a museum, or will be some day; for, in spite of a general belief to the contrary, the museum is not yet arranged, and will not, I believe, be ready for the public for some time. When at the keep last Easter I found a mere rough shell, and was told that the museum would not be ready for a couple of years or so.

Much hardship—scarcely *injustice*—must be caused to contractors by fluctuations—one way—in prices of materials; and if the fraternity could see their way to insure their own protection, no one could object. The difficulty is the bother and complication that would arise through any arrangement like that suggested by your correspondent at Birmingham. It is impracticable. Still, the question merits the attention of builders and contractors. Within a few weeks iron has risen so greatly in price that, should prices hold, any contractor requiring a large amount of constructional ironwork must be a great loser. So heavy is the rise all round, that it means ruin to some men.

In your Query columns I noticed an inquiry respecting spring ball-room floors, a subject on which information was requested, some little time back, but no information was forthcoming. Although not having had the experience of constructing a floor of this description, I recently examined an excellent spring floor in a large boarding establishment in the provinces, and carried away some idea of its construction. The whole floor was poised on a number of steel cork-screw springs, the material out of which the springs were formed being best Sheffield steel, round in section, and  $\frac{1}{2}$  in. thick; the springs, perhaps, about 6 in. high and 4 in. or 5 in. wide. The springs rested on wood plates on brick piers in the basement, and carried strong rolled iron joists, acting as binders, carrying the wood joists. The springs about 4 ft. apart. Blocks of wood prevented more than a certain amount of “play,” of which I was told there was a good deal whenever an aldermanic gentleman with a partner “inclined to *embonpoint*” passed over a spring. I have the word of reputed dancers that this floor is “delightful.”

Whether the architect be busy or not, it would upon the face of things appear that his assistant is not—decidedly not. “Linda” advertised in the professional journals at the beginning of the year for half-a-dozen assistants—a large order, as things go—and I see by his advt. in your last week’s issue, that he has received some 200 applications. This looks bad; but, possibly, like many other things, not so frightful when one inquires into matters. Doubtless many assistants already engaged, but dissatisfied, as assistants are wont to be—and I don’t blame ’em at times—applied for the berths, in the hope of bettering their position. A more likely explanation of the rush, however, and a more encouraging one would be that the list is swelled to its proportions by the large number of “improvers” applying for the two junior berths. The name of these gentlemen is legion, whatever the state of the architectural labour market, the height of the tide at London Bridge, or the price of steam-coal at the pit’s mouth. These “improvers” are gentlemen with claims on our sympathy, if getting on life; but if, as they should have done, they entered the profession sufficiently young, they are mostly of an age when a knocking-about in the world is the best possible prelude to earning one’s own living. This rough handling they, many of them—happily, I say—experience on leaving the old master’s nest. If they take the cuffs kindly, the ha’pence will seem more welcome afterwards; and the first thirty shillings for a week’s service will be handled with more pride than if they had stepped into the berth without delay and anxiety. So, as 200 into 6 won’t go, I trust that those in whose heart “Linda” has raised false hopes will not be discouraged, but at it again.

I see, notwithstanding “Linda’s” two hundred applicants, that the Salvation Army still requires more architectural assistance, their chief having advertised in your columns for two good seniors—*total abstainers*. Your advertiser has evidently never been button-holed by the ancient “Goth” with respect to a favourable reminiscence, touching a certain draughtsman—the proud possession of a poor old friend of the “A. G.’s”—who could only design in a telling manner when he was a little “on.” The effect of alcoholic liquor upon this gentleman’s powers of design

was marvellous, and his fame was great among the body of assistants, &c., to the practitioners throughout the town. It is even said that on a fine summer’s afternoon, when the sun was low over the distant ocean-horizon, knots of pupils and others would gather beneath the open window where Mr. — was at work, and listen with breathless excitement to the crisp ring of his fleet pencil, and the accompaniment of chinking glasses and loudly-popping bottles of Bass. “— is now well ‘on’!” they would whisper in awestruck tones; and could they have seen the renowned draughtsman at the moment they would have known they had not spoken in vain.

It was never my good fortune to see Mr. Blank at work, but they do say it was a sight. When thoroughly mellow, the supply of forms and features, both Classic and Gothic, was never-ending, and as he got “for’ard” the quality improved. Each different drink, moreover, produced a different design. A special tap here resulted in grand composition and outline, and one brand of “Old Tom” was noted to produce Queen Anne façades of marvellous beauty. But so long as Mr. — was well “on,” the peculiar class of refreshment mattered little. Designs of all sorts—cathedrals, churches, town-halls, public buildings—especially *publichouses*—poured forth in never-ending stream. Indeed, Blank was more than a nine days’ wonder among the pros. at Chalkton-on-Sea.

Had anyone else been able to boast of the possession of so remarkable a draughtsman, he would doubtless have been tempted to lay a special cellar, and let Mr. Blank roam therein at will. Not so my old friend. His chief complaint against his assistant was that he helped himself liberally to his master’s wines. He would tell me how his cases of wine would grow smaller by degrees and beautifully less, and how when he charged Mr. — with the spoilation, that worthy attempted not to deny the accusation. Now, recalling for the benefit of my readers generally, and the Salvation Army in particular, these historical facts about the illustrious non-total-abstainer draughtsman, it has just occurred to me that my poor friend must have kept his wine in a very peculiar place, to be accessible at all times by his assistant; and I venture, without disrespect to his memory, to suggest that his complaints were all put on, and that knowing his assistant could only design when a little “on,” he left a case of wine within easy reach. The more I think of it the more certain I become, for history assigns the position of the wine-case to the drawing-office, and who ever heard of an architect leaving wine in his drawing-office without some ulterior motive? **GOTH.**

## CHIPS.

Two stained-glass windows have just been placed in Paisley Abbey, one in memory of Robert and Thomas Speir, and the other to the memory of the late Lieutenant-Colonel Millar.

It was reported at the meeting of the promoters of the New London Tower Company, held on the 9th inst., that 248 architects and engineers are preparing designs for the Watkin tower, of whom 16 are American and Canadian and 16 French and German engineers.

A stained-glass memorial window in St. Thomas’s Church, Exeter, was unveiled on Friday. It is of three lights, Perpendicular in style, and is placed in the south aisle. The subject is Our Lord Blessing Little Children. Mr. Frederick Drake, of the Close, Exeter, was the artist.

St. John’s (Roman Catholic) Cathedral schools in York-place, Edinburgh, were solemnly blessed last week. They are an extension of existing schools and have been built at a cost of £1,500, from plans by Mr. John Biggar, architect, of Edinburgh.

A commencement has been made this week with the sewerage of the local board district of Consett. Mr. R. Robinson, of Darlington, is the engineer; and Messrs. Waddle, of Birtley, are the contractors.

On Monday the Bishop of Lichfield dedicated a new reredos at Edgmond Church. The reredos, which is of stone, depicts in the centre the Crucifixion, and at the sides are figures of SS. Peter and Paul, under crocketed canopies. The reredos is a memorial to the late Prebendary Pigott, late vicar of Edgmond, and has cost about £350. It is further proposed to complete the reredos by continuing it on each side to the chancel walls. Messrs. G. F. Bodley, A.R.A., and T. Garner are the architects, and the work was carried out by Mr. Bridgeman, of Lichfield.

## CONTEMPORARY BRITISH ARCHITECTS.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

CONTINUING our series of portraits of living architects which we commenced on the 3rd inst., we give our third sheet to-day. Taking the order followed by the arrangement of the grouping, we give a few particulars in each case before.

Mr. Wm. A. Royle, F.R.I.B.A., President for the past two years of the Manchester Society of Architects, has, in conjunction with Mr. Robt. J. Bennett, erected a great number of buildings in different parts of the country, but chiefly in Manchester and Salford, amongst which may be mentioned several schools (some of considerable magnitude) for the City of Manchester School Board; also the new offices for that Board in Deansgate, Church of England schools in Ardwick, Congregational church and school at Rooden Lane (near Manchester), Wesleyan schools in Salford, several police-stations and a branch free library for the Salford Corporation, Smedley's Hydropathic Establishment and Turkish baths at Birkdale, Southport, Turkish and Smedley baths at Harrogate, and has now in course of erection Turkish baths in South Parade, Manchester. In addition to the above he has built a large number of extensive warehouses, shops, and offices in some of the most important streets in Manchester, together with several residences in other places. The portrait here given is by Mr. Warwick Brooks, of Manchester.

Mr. John Pollard Seddon, Fellow of the Royal Institute of British Architects, born in the year 1827, was pupil to the late Professor Donaldson from 1847 to 1851, and commenced practice in London as an architect after a professional tour of some months on the Continent on the conclusion of his pupilage. In 1853, being commissioned to build an hotel at Southerndown, in Glamorgan, he became introduced to the late Mr. John Prichard, cathedral and diocesan architect for Llandaff, and accepted his invitation to join him in partnership. By degrees their joint practice became an extensive one, and continued for about ten years, during which the greater part of the restoration of Llandaff Cathedral was carried out by them, and the building or restoration of about seventy churches, forty parsonages, and seventy or eighty parochial schools and other public or private buildings in the counties of Glamorgan, Pembroke, Monmouthshire, and elsewhere. They jointly obtained a premium for £200 for the design they submitted in the competition for the Foreign and War Offices in 1857. After this they opened a branch office in London at No. 6, Whitehall, of which Mr. Seddon took charge, Mr. Prichard remaining at Llandaff. Among the more important works conducted by the firm were Eaton Park, Warwickshire, the seat of Mr. E. P. Shirley; additions to Beckford Hall, Gloucestershire; and the erection of Christchurch College, Brecon. In 1863 the partnership was dissolved; Mr. Seddon soon afterwards married, and removed to 1, Queen Anne's Gate, Westminster, which, known at that time as No. 12, Park-street, remained as both his office and residence until the year 1888. The principal works upon which Mr. Seddon has been engaged since 1863 comprise the restoration of the church of St. Nicholas, Great Yarmouth; the erection of the new church of St. James, in the same town; the orphanage and sanatorium of St. Peter's, Thanet, for Archbishop and Mrs. Tait. He was also employed by the Dean and Chapter of Norwich to report on the west front of Norwich Cathedral, and is now commissioned by the present Dean and Chapter to advise them as to the general arrangements of that cathedral, for which he is also carrying out the choir pulpit in honour of Dean Goulbourne. For Rochester Cathedral he designed the stall work in the nave, presented by Canon Cazenove in memory of his father. He built, and rebuilt after its partial destruction by fire, the University College of Wales at Aberystwith. Among his other works are new churches at Ayot St. Peter's, Herts; Chigwell Row, Essex; Redruth, Cornwall; Ullenhall, Warwickshire; Hoarwithy and Adfertton, Herefordshire; Redbrook, Wyesham, and Llandogo, on the banks of the Wye; the chancels of Fishponds, Bristol, and Lacey Green, Bucks; Gorse Hill Church, Swindon. He has restored the churches of Llanbadern, near Aberystwith; Sunningwell, near Oxford; Convil, near Carmarthen; Ingham and Arminghall, Norfolk;

Great Kimble, Bucks; Upavon, Wilts; Eythorne and Barfreton, Kent; St. Peter's, Thanet; Camrose, Pembroke, &c. Among his private mansions are Abermaide, near Aberystwith; Rosdohan, County Kerry; Broncroft Castle, Shropshire; Grove, Narbeth; Oxted, Surrey; Roughwood, Chalfont St. Giles, Bucks; besides numerous parsonages, including that of Christ Church, Westminster. The Birkenhead branch premises of the North and South Wales Bank is another important and characteristic work of his. Mr. Seddon, as is well known, was one of the twelve architects appointed by Government as competitors for the National Law Courts. He obtained the bronze medal for architecture at the Paris International Exhibition, 1878. In the year 1884 he took into partnership for all works in Wales and Monmouthshire Mr. John Coates Carter, and was, at the death of Mr. Prichard, appointed diocesan and cathedral architect for Llandaff. The firm is now conducting the important works of the complete remodelling of Chepstow Church, Caerleon Church, new churches at Grangetown, Cardiff, and Penarth (near Cardiff); alterations to St. Fagan's, and works in numerous other towns and villages in the diocese. Mr. Seddon has for several years not only designed, but superintended closely, the execution of stained-glass windows at Messrs. Belham's, 155, Buckingham Palace-road. As an author he has published "Progress in Art and Architecture" (D. Bogue, 1852), illustrated by lithographs drawn on stone by himself; in 1857 he published "Memoirs and Letters of the Late Thomas Seddon, Artist" (Nisbet and Co.); and in 1868 "Rambles in the Rhine Provinces" (John Murray); with other smaller works and contributions to professional journals, and the *Transactions of the Royal Institute of Architects*, of which institution he held for nine successive years the position of honorary secretary. Since and including the year 1887 he has been the art editor of the only monthly architectural English journal, the *Building World*. Mr. Seddon's photograph is by the Vander Weyde Light Co., Regent-street, W.

Mr. George T. Hine, F.R.I.B.A., President of the Nottingham Architectural Society, is the architect of the Claybury Asylum at Woodford, Essex, now being built for the London County Council. The contract for the superstructure was £337,945, without foundations, subways, &c., which were the subject of another contract. These works, and the lodges and boundary walls, cost £50,000 more. Besides the Claybury Asylum, which is the largest building of the kind ever erected at one time, Mr. Hine built the new Borough Asylum at Nottingham, and has just added a wing to it at a cost of £40,000. He has likewise enlarged the Coppice Lunatic Hospital, which was built thirty years ago by Mr. T. C. Hine, F.S.A. In conjunction with his father, Mr. G. T. Hine has erected, among other works, the Notts Shire Hall and Assize Courts; restored Nottingham Castle, and converted the building into a museum of arts; he has laid out the Duke of Newcastle's Nottingham Park estate, and erected thereon between 100 and 200 private villas and mansions, costing each from £1,000 to £10,000; four large board schools for the Nottingham School Board, and some more for the Newark School Board; Norbury Hall, Derbyshire; restorations of numerous churches, and two new ones in the neighbourhood of Nottingham; also the erection of several vicarages; Cranfield Court, Beds.; and several warehouses, factories, and shops, &c., including a large block of shops and offices near London Bridge. This likeness was taken by Messrs. Alfred Cox and Co., Nottingham.

Mr. R. Herbert Carpenter, F.S.A., Vice-Chairman of the Standing Committee for Art at the R.I.B.A., was articulated to the late W. Slater, and was with him in partnership until his death, December, 1872. He subsequently took a partner, Mr. B. Ingelow. The following is a list of his works:—A. Colleges and school buildings:—Jesus Coll., Camb., new students' buildings, fellows' houses, and restorations of old buildings; Lancing College, chapel, school room, and other buildings; Denstone College, chapel hall and complete buildings; Ardingley College, chapel, hall, and complete buildings; Hurstpierrepont, chapel and head master's house; Ellesmere Coll., hall and quadrangles; Dewsbury School, schoolroom; Abbot's Bromley (Girl's Middle Class), chapel and other buildings; King's School, Sherborne, schoolroom, chapel, and other buildings; King's School, Ely, Hereward's

hall, hostel, &c.; King's School, Bruton, classrooms, dormitories, &c.; Worktop College, designs for execution; St. Mary Abbot's, Bromley, designs for execution; Cheam School, chapel, dormitories, and other works; St. Kath. Coll., Tottenham (S.P.C.K.), chapel. B. Houses:—20, Arlington-street, for Lord Salisbury; Seacox Heath, for the Right Hon. G. J. Goschen, M.P.; Simonstone, for the Earl of Wharfedale; Stoughton Grange, for Mr. H. L. Powys-Keck; Hawkwell-place, for Rev. R. S. Tabor; Stanhill Court, for Mr. W. Young; Knoyle House, additions, for late Mr. K. Seymour; Trent Manor House, additions, for late Mr. K. Seymour; Brigstock Manor House, restorations, for the late Duke of Buccleuch; Sexey's Hospital, Bruton, enlargements; Yeatman Hospital, Sherborne; Digby Hotel, Sherborne; London Female Penitentiary, new buildings; and many parsonages, houses, schools, &c. C. Churches:—Armagh Cathedral, restorations; Sherborne Abbey Tower, restorations; Honolulu Cathedral; Manchester Cathedral, designs for the late Bishop Fraser (1873); Chichester Cathedral, Lady-chapel, reredos, &c.; Worktop Abbey Church, designs for its restoration, for Duke of Newcastle; Newmarket Memorial Church, for the Duchess of Montrose; Felham; Brighton, Church of the Resurrection, and spire to St. Paul's, in West-street; Enfield, St. Michael's; Dunston, for the Earl of Ripon; Hardrow, for the Earl of Wharfedale; Long Marston; Outrington; Bootle; Belfast; St. Martha, Paddington Church, Lawford; Sutton. Churches restored:—Market Drayton; St. Leonard, Bridgworth; Earl's Barton, Brigstock, Blankney, Henfield, Bruton, Cranbrook, Sandhurst, Strixton, Middleton, Child's Ercall, Aldrington, Tring, Southover, Gem Magna, Thurnby, Stapleton, Barton Latimer; many churches for the late Duke of Buccleuch and for the late Mr. G. D. W. Digby; restorations of gate tower and fittings at St. Augustine's Coll., Canterbury; and many works for the late Right Hon. A. J. B. Beresford Hope, including his memorial. The portrait herewith reproduced was executed by Messrs. Dickinson and Foster, New Bond-street, W.

Mr. W. Henry Lynn, R.H.A., President of the Royal Institute of Architects of Ireland, 1886-9, was the architect of the Town Hall at Chester, with the market front adjoining; the Geo. A. Clark Halls, with the bridge adjoining them at Paisley, the new municipal buildings at Barrow-in-Furness, and the public library buildings at Belfast. The commissions for these works, as well as for others of a less important character, were the result of successful competition. His design was awarded the first prize in the International competition (1861) for proposed Houses of Parliament and Government offices at Sydney, N. S. Wales. In the Plymouth Guildhall Competition he received a second premium, and in the competition for the Glasgow Municipal Buildings, his design was placed third in order of merit. In the Birmingham Municipal Buildings and Assize Court Competition (1871), Mr. Lynn, by proposing to connect the new buildings with the existing town hall, was considered to have taken a too liberal view of the margin of deviation allowed by the instructions; hence his design, which otherwise was regarded as the best, was disqualified. As partner of the late Sir Charles Lanyon up to the year 1872, and individually since then, Mr. Lynn has enjoyed a large general practice in Ireland. In 1875 he was invited by Lord Dufferin, then Governor General of Canada, to visit Quebec to advise on contemplated improvements there, amongst others a viceregal residence (a new Chateau St. Louis) to be erected in the citadel, for which he prepared designs. For many years Mr. Lynn was a Fellow of the R.I.B.A., but with other Irish architects he withdrew when the old arrangement of differential subscriptions for town and country members was set aside, the change being regarded by them as unjust to practitioners so far removed from the advantages of London membership. The photograph of Mr. Lynn is by Mr. Magill, of Belfast.

Mr. Henry Crisp, F.R.I.B.A., the President of the Bristol Society of Architects, was years ago in partnership with the late E. W. Godwin, F.S.A., and is now working in his practice with Mr. Oatley, of Bristol. Among his works are the following:—Extension of Bristol Royal Infirmary; extension of Bristol General Hospital; nurses' home at Bristol General Hospital; large extension at the Bristol Lunatic Asylum, now in progress; large Police-station, Bedminster,

Bristol; large showrooms, offices, and extensive manufacturing premises for the Bristol Waggon Works Co.; large printing works at Bedminster, Bristol, for Messrs. Robinson and Co., lithographers; block of offices, Clare-street, Bristol, for the Western Wagon and Property Company; mansion at Henbury; extension of the Bristol Eye Hospital; sundry church works, schools, vicarages and other residences, banks, business premises and warehouses, &c. During Mr. Crisp's partnership with the late Mr. E. W. Godwin, the firm carried out Dromore Castle for the Earl of Limerick (*BUILDING NEWS*, Vol. XIV., pp. 224 and 758); Glenbeigh Towers in Co. Kerry, and some lodges and buildings at Castle Ashby, for the Marquis of Northampton. The award of the Bristol Assize Courts competition by Mr. Alfred Waterhouse, R.A., was extraordinary in the history of such matters, as Messrs. Godwin and Crisp won all three premiums—viz., £100, £50, and £30—with three designs, which were placed first, second, and third by the referee. The site for the building was subsequently increased, and although Mr. Waterhouse advised the authorities that either one of the prize designs could be adapted to the enlarged site, his report was ignored, and another competition was held. Messrs. Godwin and Crisp were awarded the second premium, but Mr. Waterhouse did not act as referee. Mr. Crisp's portrait was taken by Mr. Protheroe, of Bristol.

#### CARPENTRY AND JOINERY.—XXVI.

##### CASEMENT FRAMES AND SASHES.

THESE are used for lodges, cottages, villas, clubs, and many kinds of public buildings, as well as in other situations; and as the above uses which they are put to will indicate, there are many varieties.

It cannot be expected that more than an outline of the leading kinds will be given. To take

Fig 178

2" Scale

an example of one used for dormers in a country mansion, Fig. 178 gives a section through the sill of the frame, and also the sash sill. These dormers were executed in oak, being framed square, and the frame being double-tenoned; the sash had two tenons in the sill through the stiles, and the junction of head and stile was made with two dovetails.

Fig. 179 is a section through the stiles and head, of which Fig. 178 is the sill; the grooves in the inner edges of stiles, head, and sill are for the internal finishing, or may be used for a key to the plaster if a plainer finish is required. The rebate in the front or outer edges of the stiles and head was for the finishing of the outside, which consisted of a flat plate 1½ in. thick fitted into the rebate of each stile, the top or head being tenoned into the stile pieces; another piece was returned from these two stile pieces at right angles or parallel with the stiles of the frame, and the angle formed by the union of these pieces was moulded, the moulding being stopped on a level with the daylight of the glass in the sash.

Fig. 180 gives a section through the stile and head of the sash, the arrangement for the plate-glass is seen, as also the moulding by which it was kept in position, and which is omitted in the section of the sill. It will be readily understood on account of the outline of Fig. 180 that it required careful and accurate workmanship in fitting the sash together, the sill was dowelled, but the head was not; no place fitting for that occurring.

The sides of the dormer were sheeted with

2½ in. sheeting, the roof being hipped. Inside the sheeting were nailed *brandering laths*, to which were nailed the plaster laths.

Sometimes dormer-windows are semicircular on the top, in which case either there are two sashes in width, or else the semicircular portion, or segmental, should that occur, is as a sash made a fixture, and the under rail rebated and throated on its under edge for the other portion or portions to strike against, and often to have part of the fastenings fixed upon it. It will be found in

Fig 179

2" Scale

Fig 180

3" Scale

the making of a segment-headed sash, when the head is of the same section as the stiles, that a peculiar construction is required.

Fig. 181 shows how the connection is made. It will be seen by the edge and end view that a dovetail is worked on the head, and provision made for it in the stile; in wedging-up a dowel is put through. Some workmen

Fig 181

2" Scale

attempt this junction with a bevel mortise through the stile and the tenon parallel with the run of the edge; but it is almost, if not quite, impossible to wedge it up satisfactorily, and the space is generally too contracted for a square mortise. Some make this same connection in a similar way to that described in connection with, and shown in,

Fig 182

2" Scale

Fig. 177, with the difference that the mortise is bevelled as described in the previous sentence, and no attempt is made at wedging but simply dowelled when *cramped up*. The example of casements given at the beginning of this article is one in which the sash opens outwards, and this is very easily kept water-tight, as the rebating and throating are usually sufficient; the rebating may be deepened, as also the throating, in very exposed situations. Provision may be made for condensed water by a gutter hollowed out in the sill of the frame, and a hole may be bored con-

necting this gutter with the outside of the building, and a pipe or tube inserted into this will carry off the condensed water. This tube will require to be cleared occasionally, as it will get filled with dust or dirt.

It will be readily understood that in the case of sashes in casement-frames, and which are hinged, they will require to be of such width as that when open they will not project so far as to be in the way, nor offer too much surface to the wind, thereby risking the glass, and in case of a very violent storm coming on hastily and the casement being open, even risking that the sash may be torn from its hinges. These conditions are usually observed, either because mullions are

2" Scale

introduced into the frames, or the sashes are made to hang folding when a wide casement-frame is needed. One little matter to be attended to in casements is the fastening; a common method in inferior or common work is by means of a quadrant; a small tower or flush bolt may also be used. The tower bolt can be had with a *crank*, if more suitable. As suggested, sometimes the sash of the upper part of the casement is either made fast or otherwise hinged; in such case the "Silens," as advertised in this journal, may be used, or other of the several appliances for the purpose in the market.

Fig. 182 gives a section through a casement frame and sash suitable, say, for a lodge. The drawing is self-explanatory; but the section of the moulding on the right is introduced to show what may be used as a kind of mullion. It forms a striking surface for the sashes where they meet

Fig 184

2" Scale

in the middle, and, given an outline of casement such as Fig. 183 to provide for, it serves for carrying across the horizontal line, forming a kind of transom.

Fig. 183 shows by dotted lines a tenon, and this is how the connection is made in this moulding. The members of the moulding can be either mitred or scribed, and a dowel could be put in from the plain side through the tenon, but not coming through, as that would generally disfigure the moulding; a screw could be inserted instead, if preferred. The factory light may almost be styled a kind of casement, as in most cases it has a fanlight which opens for the purpose of ventilation, and sometimes sashes are introduced into it. Again, it may be divided into small squares for the purpose of cheapening the glazing, and so that should a square of glass be broken by a stone or other missile it will cost little to replace it.]

Fig. 184 gives a section of an outer stile and centre bar, common enough for a factory or workshop. If the timber is of sufficient dimensions, this frame can be tenoned together at the angles; but, if not, it can be dovetailed and doweled. The inner bars will be tenoned into the stiles head and sill, supposing it to be divided, say, into four squares. The ventilating fanlight will be dealt with immediately.

Fig. 185 gives two illustrations to show how the inner bars in the above light can be joined. It supposes, as a first case, that it is only square, a gap or check is cut out of each half way through, and exactly the thickness of the piece the other way, then they are driven together at right angles.

Fig. 186 is intended to represent that, in addition to the halving, a scribing is also made—that is, as much is cut away as just to allow the bar to fit in, according to the section shown of the centre bar in Fig. 184. In this way we have a halving and scribing, which has the advantage of allowing the bars both to be continuous, and being tenoned into the head and sill and stiles respectively, close joints are obtained at the junction of the dividing bars, which is almost impossible unless the outer stuff is very heavy. When mortising, tenoning and scribing is resorted to at the joining of the centre-bars, instead of halving and scribing. When the casement is divided into many small squares, this method of halving and scribing is resorted to,

Fig 185

1" Scale

and even when the bar is bevelled from the rebate for the glass without any square, this method will serve. It can also be adopted with certain kinds of moulded bars.

Fig. 187 gives the illustrations in connection with the ventilating fanlight of these lights, that on the right being the section of the stile to show (which is done by a double line) that the stile at the part is just split or divided, half of it continuing unbroken to the head, and the other forming the stile of the fanlight. On the left is shown the transome (may we call it?) formed by the bottom rail of the fanlight and the cross rail of the casement. The illustration is self-explanatory. The head is similar, only the top rail of the fanlight is of the same section as the cross rail of the casement shown here, and the head of the casement is rebated to match. This will be clear when it is remembered that the fanlight is hung on pivots, and the pivots are usually placed a little higher than the centre, so that the fanlight will shut of its own weight, a cord being attached to an eye or ring in the fanlight to pull it open, and a *belaying-pin* being screwed to the stile of the casement for fastening a cord to when the fanlight is open at the required angle. The joiner will have no difficulty in putting on the pivots; they are, of course, placed centrally in the width of the stile of the casement. The simplest kind of pivot is that of which there are *rights and lefts* (pairs) of the same form; in these the plate screwed on the frame has an inclined cut, leading down to the hole in which the axis of the pivot works. With these the fanlight can be put right in, whereas in the kind that requires to have the fanlight put in at one side first, there must be more space allowed for *freedom*, which anyone will know is objectionable, as it will allow of the freer entry of rain and wind. Now, as all casement sashes do not open outwards, those which open inwards (and they are numerous) have to be differently arranged in their details.

Fig. 188 gives an illustration of that which is adopted sometimes under such circumstances—

viz., a circular groove is wrought in the frame-stile, and a corresponding round is left on the stile of the sash. The sash is hinged to open inwards; hinge is not shown, but the bead, which is seen on the sash-stile, would correspond with the *knuckle*, or round of the hinge. It will be seen that the circular groove wrought in the stile of the frame serves, as it were, to give an additional depth to the rebate, thus affording additional resistance to the weather, and the

Fig 186

2" Scale

groove itself acts as a conductor, or waterway, for any water which may be driven in, and by means of which it flows down into a similar but larger groove in the sill.

Fig. 189 shows the arrangement of the sill, as also how the sill of the casement-sash occurs. It is seen that the sash-sill is furnished to the outside with a throated water-bar in the form of a

Fig 187

2" Scale

moulding by which the water which flows down the sash is thrown into the weathering of the sill of the frame, the throating breaking the passage of the water which might flow in along the joint between the two sills, and any which might pass along falls into the groove in the sill of the frame and is conducted out by the pipe which

Fig 188

2" Scale

leads from this, and shown by dotted lines in the figure. This groove and pipe serve also to carry off the water which flows down the grooves in the stiles. Fig. 189 shows also the flooring, and this is a little lower than the top of the sill, in order that the sash in opening may swing clear of the carpet. The transom or the head of the frame, as the case may be, need only be rebated or cheeked square, as the water is not likely to find its way in at that place; but as an additional

preventive a throating can be introduced. There are other modifications which can be and are adopted. The fertile mind can readily produce other details to obtain similar results to those intended by the above illustrations. Patent water-bars and the provision made for them in French and other casements have not been discussed, and this is considered unnecessary, as the readers of the *BUILDING NEWS* must be familiar with the advertisements setting forth the merits of these and the drawings or illustrations accompanying the announcements are self-explanatory.

There are several of these "patent water-bars" in the market, and the workman can readily find the merits and demerits of each, and

Fig 189

2" Scale

decide which to adopt in case the choice is left to him; but the particular kind is usually specified by the architect.

Some building firms have models of "patent water-bars," so that the workman can obtain from the foreman's office the necessary information to enable him to work out the difficulty if he has any in this direction.

#### UNITING BUILDINGS.

THE frequent opportunity that occurs in London and other large towns to acquire a row of private houses for the purpose of conversion into business premises is fraught with mischief which our present legislation is scarcely equal to grapple with. The process is easy and comparatively inexpensive. A new firm of, say, drapers take one or two houses in a good thoroughfare; they open a business which proves a success, and then extend their operations by acquiring the houses on one or both sides of them. Less expense is involved in this transaction than purchasing a site and building new premises for their express wants. The houses can be acquired probably at a moderate rental, and their alteration does not entail a very heavy expenditure to fit them for business. The old shops side by side are made into one large shop by making openings through the party-walls, and the same plan can be adopted in turning the first floor rooms into show-rooms. To economise space, the staircases are reduced; instead of five or six, one to each house, only two are allowed to remain. The upper stories can be sublet, or turned into dormitories, at a trifling cost. The Building Acts do not impose any serious difficulties in the way of converting private into business premises. The Acts only say that buildings so united shall be wholly in the same occupation, and that when united they shall not be in contravention of any of the provisions of the Acts. Referring to openings in party-walls, the clause states: "No opening shall be made in any party-wall dividing buildings which, if taken together, would contain more than 216,000c.ft., except under the conditions that such openings shall not exceed in width 7ft. or in height 8ft., and the floor jambs and heads of such openings formed of brick, stone, or iron, and be closed by two wrought-iron doors, each  $\frac{1}{2}$ in. thick in the panel, at a distance from each other of the full thickness of the wall, fitted to rebated iron frames." So that

the gist of the rule is that provided the openings do not exceed the area stated, and are made with fireproof materials, any number of houses can be united. With regard to the iron doors, who is to see whether they are ever used or closed at night? And we have in evidence the fact of such doors having not even been fitted. The best proof of the manner these provision have been carried out is to be found in the records of fires such as those in the Edgware-road, where the alterations appear to have been made without any provision for the egress of those using the dormitories. In this instance a number of shops had been acquired one after the other, the party-walls had been cut through indiscriminately to make show-rooms, and the only means of exit for the unfortunate victims were the windows of one house, the staircases having been removed.

The craze there is for building enormous shops and stores has quite rendered the provisions of the Metropolitan Building Act powerless to deal with the evil. Even experienced surveyors state that it is very doubtful if the restrictions of the Act can be legally enforced in the case of large retail shops and stores. We do not think they can, as the Building Act clauses, under the 28th section, are intended to prevent the uniting of several buildings for warehouses of greater cubical capacity than 216,000ft., and had no reference to the adding of shop to shop. Houses or shops acquired one after the other for extensions of business may take some years; the alterations are generally effected in a piecemeal way—a doorway may be made through one party-wall, then enlarged; partitions may be taken down by degrees, without the knowledge of the district surveyor. In this manner a number of large business premises are formed—certainly never built. The district surveyors often try to make builders conform with the rules for warehouses, but without effect. A very common practice is to enlarge the openings allowed by statute in party-walls, till they gradually disappear or are practically of no account in case of a fire.

The removal of the means of exit in united buildings is one of those things also which the existing statute does not prevent, or is powerless to interfere with. Surely the proposed amendments of the County Council ought to have included a provision for this subject. The Council should have made a provision compelling everyone who unites premises beyond a certain area to provide proper means of exit from the upper stories. There is one proposed amendment giving the Council power to permit the erection of a building without party-walls used for trade or manufacture including more than 216,000c.ft.; but the space is not to exceed 450,000c.ft. This is a very large space to be left undivided, and should only be allowed under particular conditions; but the question of the most urgent importance is to what limit it is safe to allow owners or tenants of premises to unite them for business purposes without substantial alterations. The walls of single houses are scheduled for certain lengths and heights, and are too thin for warehouse uses. By allowing partitions to be removed internally and additional stairs built, their limits of strength may be often exceeded, and they should be properly made thicker to endure the stress put upon them, and to be secure in case of fire. No safer rule can be insisted upon in uniting buildings than that they should have their party-walls interfered with as little as possible, and that the openings allowed by statute should be protected in the manner stated; and, secondly, that proper staircases should be placed in positions readily accessible in lieu of any removed. In regard to the custom to which we refer, of joining a dozen or more houses, no legal obligations appear to be in force.

#### LEWANNICK CHURCH, CORNWALL.

THE parish church of Lewannick, about six miles from Launceston, was destroyed by fire early on Sunday morning. The church was rebuilt in 1546—at least, the fine oak carved benches by which the body of the edifice was seated bore that date. As an excellent example of what Mediaeval seating was, the benches at Lewannick, now unhappily totally destroyed, were the best example in the West Country. The chancel was restored in 1880, at the expense of the vicar, by Mr. Harry Hems, of Exeter. The church consisted of a tower with a nave, north and south aisles, small vestry-room, two porches, and chancel. The tower and walls,

with the pillars marking the north and south aisles, the small vestry and the porches, are the only portions now remaining. The disastrous fire was caused in the customary manner, by the overheating of timber which touched the flue of the warming apparatus. The bells were injured by heat beyond possibility of use without recasting. All the monuments on the south walls were destroyed. On the north wall two modern memorials escaped. The porch on the north side is not much damaged, and the font sustained only a crack, the result of intense heat. The walls of the church will probably need reconstruction, and the tower, if allowed to remain, will need costly repair. The church was not insured. Fortunately, the Communion plate and the registers, dating from 1661, were at the vicarage. All antiquarians will be glad to know that the famous cresset stone in this church, wholly perfect, and with 7 cup-like holes, to which attention was first called in this journal by Mr. Hems some ten years ago, was, through the gallantry of the vicar, saved from the burning edifice, and is now quite intact and none the worse for the fiery ordeal it has passed through. It was illustrated in the BUILDING NEWS for July 18, 1879. Examples of cresset stones are extremely rare in this country. The nearest ones to Lewannick are at Wool, in Dorset (with 4 cups), and at St. Mary's, Monmouth (6 cups). At Calder Abbey there is one (16 cups); also at Carlisle Cathedral (6 cups), and at Furness Abbey (5 cups). At Llanthony Abbey is a cresset stone (3 cups), at St. Mary's, York, another (6 cups), and at Dearham Church, Cumberland, is also an example (1 cup). This probably completes the list in Great Britain. In the Stockholm Museum, however, there are four cresset stones (labelled "Vigoatens-sten"—i.e., holy-water vessels); one with 4 cups and another with 5 are both of unknown origin. Of the others, one comes from Balla Church (6 cups), and the other from Onaruds Church (6 cups). In the diocese of Sund, in Sweden, two cresset stones are still *in situ* in local churches—i.e., at Nöbbelofs (6 cups) and at Strö (5 cups). This latter is not unlike the Lewannick cresset. The latter, however, is the most perfect specimen in existence; and, therefore, it is the more fortunate that it has been rescued from the peril it was in last Sunday morning.

#### CHIPS.

The Art Gallery Committee of Wednesbury have accepted the tender of Mr. H. Wilcox, of Wolverhampton, for the building of the Wednesbury Art Gallery, for the sum of about £3,400, which is somewhat more than was at first estimated would be required for this purpose, but the increase is accounted for by recent advances in the prices of materials and rates of wages. Mr. Wilcox was the builder of the Wolverhampton Art Gallery.

The Liverpool City Council, at their last meeting, finally adopted a new code of building by-laws which has been approved of by the Local Government Board.

The local board of Smethwick decided, at their last meeting, to instruct Messrs. Harris and Harris, civil engineers, of Birmingham, to prepare a scheme for lines of sewers in the streets of the portions of the district adjoining the city of Birmingham. At the same meeting Mr. C. J. F. Allen was appointed assistant surveyor.

A spiral front cover of pierced and open tracery has been placed over the 15th-century font in Awliscombe parish church as a memorial. It has been executed in oak by Mr. Harry Hems, of Exeter.

On Tuesday week Col. W. M. Ducat, R.E., held an inquiry at the Guildhall, Stafford, on behalf of the Local Government Board, as to an application by The Town Council to borrow an additional £4,400 for waterworks purposes. The Town Clerk stated that altogether £40,000 had been spent upon the various water schemes, and the further loan, which would make a total of £42,000, was necessary to complete the work. He added that after all their troubles, disappointments, and mistakes the water supply would not cost above £2 a-head of the population, a sum which was less than the average cost throughout the country.

The church tower of Bodmin was reopened on Wednesday week, after restoration. The work consisted of new pinnacles in De Lank granite, a new vestry within the tower, and general repairs and repointing throughout, at a cost of about £400. The contract was intrusted to Mr. N. Shelly, Bodmin, and the plans were prepared by Mr. John Dennis. The granite work was executed by Messrs. Bate and Son, of Cardynham.

## Building Intelligence.

**BIRKENHEAD.**—While the Mersey Tunnel excavations were in progress beneath Beckwith-street, Birkenhead, the work caused a sinking in the foundations of St. Lawrence's Roman Catholic Church, which was situated at the corner of Beckwith and Park-streets. So serious did these disturbances become that the church had finally to be pulled down, arbitrators having decided that the railway company should pay £8,000 damages to the trustees (of which, however, only £3,500 has been handed over), and on March 17th, 1889, the foundation stones were relaid on a new site, about 60ft. removed from the old one. Since that date Mr. J. Shaw, Priory-street, Birkenhead, has been rebuilding the church to the plans of Mr. Edmund Kirby, Cook-street, Liverpool, and the new edifice has now been opened. The building differs somewhat from the old one, but all the materials used have been those of which the older place was constructed. The old church was of one span from wall to wall, but the new one has been built with nave and aisles. A chancel has been added, and the total length is now 130ft., width 60ft., and height to the apex of roof inside 70ft. The church is Gothic in style, and is built of stone. All the old fittings, entrances, and window frames have been used. Mr. H. L. Whittingham was the clerk of the works. The glasswork throughout the church has been done by Mr. Lockland, Conway-street, Birkenhead, and the inner fittings by Mr. W. Johnson and Mr. Herbert, of Messrs. Herbert and Cox.

**KENSAL GREEN CEMETERY.**—The church and chapel of this cemetery have been redecorated. The former being much larger and more architectural in its features, is the more important work of the two. The style of the building is Greek Doric of a severe type, and the details of the work have, as far as possible, been assimilated thereto. The dome or vault, which is fluted, is treated in a cerulean blue as a ground powdered with gold stars in the flutings. The walls are toned in various shades of cream, of nut and russet browns and cinnamon, relieved by stencillings of brighter hues, the salient features being gilded, as the structure is none too light in dull weather. The Alpha and Omega are introduced here and there to give Christian character to the work. The east window (not really east, we fear) has a painted representation of the Risen Saviour in a style of art which is not now in vogue, but as a relic of the early days of the cemetery it has been allowed to remain. A handsome organ has been provided for those cases, increasing in number, where the addition of music to the funeral office is desired. The scheme of decoration has been carried out by Messrs. Hayward and Son, art decorators, Newgate-street, under the supervision of the architect, Mr. Robert Willey, F.R.I.B.A., 66, Ludgate-hill.

**SALFORD.**—The Town Council have adopted plans for a new infectious hospital, to be built on a plot of land, about 13½ acres in extent, situated at the extreme south-west corner of the borough, between the Eccles New-road and the river Irwell. The chief feature of the buildings will be three pavilions, in which provision will be made in six "acute wards" and six "convalescent wards" for 144 beds. At the south end of the convalescent wards there will be inclosed balconies, from which a fine view of Trafford Park will be obtained. The corridors between the wards are to be unusually wide, and they will be divided from the wards by plate-glass partitions, so as to permit friends to see the patients without danger of infection. There will be two isolation blocks, which will contain provision for 40 patients, bringing up the total accommodation to 184. The administrative departments, as planned, will be sufficiently large to provide for 48 additional patients, without any extension. The total cost is estimated at £50,000. The plans have been prepared Messrs. Maxwell and Tuke and Messrs. E. and F. Hewitt, of Manchester, and the work will be carried out under their superintendence as joint architects.

A series of special articles on "The National Monuments of Ireland," from the pen of Mr. T. H. Deane, R.I.I.A., is appearing in the *Dublin Daily Express*. The first paper was published on the 1st inst., and dealt with Cashel Cathedral, Hoar and Holy Cross Abbeys, and the Priory at Athassail.

## ARCHITECTURAL &amp; ARCHÆOLOGICAL SOCIETIES.

**EDINBURGH ARCHITECTURAL ASSOCIATION.**—A lecture on "Some Early Scottish Architects" was given by Mr. J. Balfour Paul, advocate, to the members of this Association, on the 9th inst. Mr. H. J. Blanc occupied the chair. Having pointed out that few records as to the designers of our cathedrals and castles were available, the lecturer proceeded to mention some of the more prominent of Scottish architects of early times. Gilbert of Moray, Bishop of Caithness in the first part of the 13th-century, had the credit of designing and building at his own charges the church of Dornoch, the remains of which were still in existence, incorporated with the present parish church. The Castle of Kildrummie, in Aberdeenshire, was also probably erected by him. In the 15th-century a family of the name of Merloun was largely employed by the king in executing work at Stirling Castle, Dunbar, and other Royal fortresses. Thomas Cochrane, the favourite of James III., who fell a victim to the vengeance of Angus and other nobles, was stated to have been an architect, though his exact position in the King's household had always been doubtful. Another architect of that century, Sir James Hamilton, of Fyvirait, came to a violent end, being executed on a charge of inventing an infernal machine by which the king was to be shot from the tower of Linlithgow. A distinguished man, William Schaw, held the post of king's architect to James VI., and he restored Dunfermline Abbey, and was buried there. After alluding to some of the nobles who were instrumental in erecting the leading mansions and castles of Scotland, the lecturer gave an account of the family of the Mylnes. Belonging to Aberdeen, they gradually came south, and in the 17th-century John Mylne was located in Edinburgh, and was member of Parliament for the city. He was buried in Greyfriars' Churchyard. His nephew Robert was the builder of Mylne's Court, and several other premises in Edinburgh. A descendant of his built the North Bridge, and another attained eminence in his profession in London. The lecturer subsequently made reference to the claims put forward for Inigo Jones, Wallace, Aytoun, and Balcanquhall as the designers of Heriot's Hospital. He also spoke of Sir William Bruce, of Kinross, who restored Holyrood in 1671. In conclusion he gave sketches of James Gibbs, Colin Campbell, and the elder Adam.

**MANCHESTER ARCHITECTURAL ASSOCIATION.**—The members of this society met on Tuesday evening, and Mr. Lawrence Booth, F.R.I.B.A., a past president of the association, read a paper on "Commission." The paper dealt with the subject of commission as understood and practised in business life, treating it in its several degrees of legitimate, through the questionable, to that of absolute dishonesty; and indicated that many industries were groaning under the effects of the latter, as an incubus preventing their progress and prosperity. In its application to architectural practice, he deprecated all secret commissions, and advocated complete candour on the part of the architect towards his client, as "suspicion always dogged the steps of secrecy." The author protested against a very general imputation that architects, being paid by commission, brought about extra expenditure in order to increase the amount of their own charges, and asked men of the world to consider for a moment whether any architect so depraved as to be willing to squander his client's money, in order that a shilling in every pound would find its way into his own pocket, would not be likely to devise some more simple and less palatable method of robbing his employer. Extras of a preventible character did make their appearance, and were frequently the result of the desire of architects, especially new beginners, to put in "all they know in the way of decorative features and good architectural effect," in the hope of enhancing their own professional reputation. Such efforts had frequently the opposite result, and ought to be avoided, but fell very far short of deserving the condemnation bestowed on gross and corrupt motives. The main argument of the paper was directed against the remuneration of architects being regulated by the amount of money spent, or, in other words, against the principle of payment by commission, and in favour of payment by results; the writer saying, "it is, indeed, doubtful whether the community would not long since have compelled us to adopt

a more rational method in the assessment of our services if they had been less familiar with payment by commission in their other transactions."

**SHEFFIELD SOCIETY OF ARCHITECTS AND SURVEYORS.**—At the usual monthly meeting of this society on Tuesday evening, Mr. F. Fowler, the president, occupied the chair. Mr. J. B. Mitchell-Withers read an interesting paper, entitled "Elementary Notes on the Mouldings of Mediæval English Architecture." He quoted the late Mr. Sharpe's authority for the statement that English architectural history was written as much in the mouldings as the general outlines and masses of its old buildings. It was an easy matter for the architect who had diligently drawn and measured old work to understand and trace out its development from Early to Late forms. The nave of Westminster Abbey was a notable instance of the use in one general grand design of the various styles of mouldings from the 13th to the 16th century. No architect who had not an intimate knowledge of the subject ought to meddle with any old building, the humblest of which was generally a good school to study in, and young architects should diligently study and draw the buildings of their district. The late Sir Gilbert Scott had laid down that measured and full-sized drawings were far more useful to the architect than photographs, &c. The lecturer gave illustrations on the black board of the principles of grouping and designing mouldings of the different periods, and alluded to the best means of drawing them from actual work. He also noticed the nomenclature of Mediæval mouldings, quoting from William of Worcester, who wrote at Bristol in the 15th century, and the late E. J. Willson's notes in "Pugin's Specimens." The illustrious French architect, the late M. Viollet le Duc, had said "that to the practical architect a knowledge of mouldings was of the first importance," and that the mouldings of the Greeks and 13th-century architects "satisfy alike taste and reason."

## CHIPS.

The memorial stone of the Irvine Memorial Free Church at Camelon, near Falkirk, was laid on Saturday. It is Gothic in style, seats 400 persons, and has cost £1,200. Mr. G. D. Page, of Falkirk, is the architect.

At a meeting of St. Paul's Ecclesiological Society, held last (Thursday) evening at St. Paul's Chapter-house, E.C., a paper on "Mural Decoration in Churches" was read by Mr. Hamilton Jackson, R.B.A.

A memorial to Col. J. W. Watson in grey Devonshire granite and white Sicilian marble has just been placed in the Rajkot Cemetery, Bombay, by Mr. Harry Hems, of Exeter. The exterior kerb measures 11ft. by 8ft., and is of granite. The space within is filled by one slab of white marble, upon the centre of which is a coped Gothic cross, 6ft. long, and panelled with sunk trefoil at the four ends. The whole is surmounted by iron railings. The legend occurs upon the slab, and is in lead lettering flush with the face of the work.

In continuation of last year's restoration of the Church of St. Giles', Cripplegate, when Messrs. Jones and Willis made and fixed the wrought-iron screen, and the oak and ebony altar table, they have now completed the new system of lighting. The whole of the old fittings, pipes, &c., have been removed. The new system embraces lighting the nave and chancel by drops from the centre of each arch, the coronas are each of 8 lights, and are of hammered leaf work to match the screen. The whole of the work has been carried out from the designs and under the superintendence of Mr. F. Hammond, the architect to the church.

Dedication services were held in the new Swedenborgian Church in Moss-lane East, South Manchester, on the 9th inst. When the church in Peter-street, Manchester, was sold for the purposes of the technical school, it was arranged that two new churches should be built in the suburbs—one on the north side and one on the south side of the city. A site for the northern church was found in Bury New-road, and the building is almost complete. The southern church has been erected in Moss-lane East, at the end of Baby-street. The style adopted is Gothic of the Decorated period. The spire rises to a height of 100ft. Inside the church measures 76ft. by 35ft. (across the transepts 45ft.), and there is accommodation for 360 people. In the rear of the church are school premises and an assembly-hall. The cost has been about £5,500. The contractor was Mr. W. Thorpe, Cornbrook Park-road, and the architects were Messrs. Isitt and Verity, Bradford and Wigan.

## TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

## TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.) To India (via Brindisi), £1 10s. 4d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

## ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph Advertisement inserted for less than 5s.

## SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING for TWENTY-FOUR WORDS, and Sixpence for every eight words after. All Situation Advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page advertisements and alterations in serial advertisements must reach the office by Tuesday Morning to secure insertion.

## NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XLII., XLVI., XLIX., L., LI., LIII., and LVI., may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—J. A. and Son—G. E. and Co.—W. B. and Son—J. E. and Son—J. A. and Son—Prof. J. H. M.

A. B. (We really cannot supply the information you ask for.)

## Correspondence.

## SOUTH STOCKTON PUBLIC OFFICES COMPETITION: MODIFIED CONDITIONS.

To the Editor of the BUILDING NEWS.

SIR,—In compliance with the suggestions of suggestions of several architects who propose to send in competitive drawings, the Board have decided to modify their original conditions to the following extent—viz., that the plans submitted shall comprise elevations of both fronts, plans of each floor, and transverse sections with an abstract of specification, but that it is to be understood that the full requirements of the conditions with respect to working drawings and schedules of quantities shall be afterwards complied with by the three successful competitors.

In answer to several inquiries, I may say that the site is practically level; that it is quite open on three sides, but that on the east side there is a house and shop; so that it will be necessary for the purposes of light to leave a sufficient area on that side.

I am desired to say that if the terms offered are satisfactory and there are no sufficient reasons to the contrary, the Board propose to employ the successful competitor to carry out the work.

The Board hope that these modifications will meet the wishes of all competing architects.—I am, &c.,

W. J. WATSON,

Clerk to the Board.

## HINTS TO A YOUNG ARCHITECT.

By AN OLD BUILDER.

SIR,—A sense of paternal duty lately led me into making a number of private notes on the "Don't you forget" principle on things "not generally known" by young architects—things

simple in themselves, but none the less essential; practical things, the neglect of which an experience of well-nigh half a century has taught me is too common; not matters of art or style—of these I know little—nor yet such matters as are necessary to be studied to pass the “exams.,” but such as may be found—but I don’t know where—in costly or ponderous books, but require too much looking for by ordinary readers—cautions with advice, in short, as to construction, materials, &c.

Having during the time I have named carried out an all-round sort of business in town and country under architects of all sorts and conditions, I should either be very forgetful or very stupid if I did not know of “blunders many,” both my own and others; so the thought struck me to ask through you if anyone knows of a published work on these lines, not in a voluminous, but in a terse, concise form, the more direct the better. To make my meaning more clear, I will give one or two from my “Memorabilia.”

**Levels of Site.**—See these are taken and shown correctly before, and not after, contract is let. Often neglected. A frequent source of trouble and “extras.”

**Cavity Walls.**—See they are cut-off between stories. Have known bed-rooms almost unuseable from this source. Cavities conduct sound.

**Dry Rot.**—Provide through ventilation, not only in uncellared portions, but round timbers bedded in walls.

**Foundations.**—Unsafe not only on previously disturbed soil, however remote, but on some stiff clays, given to cracking in hot weather. Have known such cracks 7ft. deep. Concrete preferable to either brick or stonework foundations.

What more useful to many than a column in your pages headed “Blunders I have Known,” if only those qualified would only contribute to it. My experience is meagre as compared with many of my fellow builders, yet how seldom do we profit from anything in print from them? Is it my limited vision that leads me to say this, or is it we are too much engaged in this “helter-skelter competitive age” to give it the time, or is it a tinge of selfishness in not giving gratis what has doubtless cost them much? A sense of advantage to those coming after us ought to overcome this. It may be, and I fancy often is, a fear of criticism, or being unable to write for the Press. All I can say is, of the first, if fair, and not vulgar or personal, it is generally refreshing and instructive. As to the latter, let them try, as I have, and see how indulgent the Press can be, particularly in putting into readable shape what otherwise might hardly be so. I have often been astonished to see my homespun material so well put together.—I am, &c.,

R. B.

#### ANOTHER ADVERTISING “ARCHITECT”!

SIR,—The advertisement of which a copy is appended appeared recently in a paper published in the Isle of Man. Comment is needless. The last words actually appear as a kind of footnote.—I am, &c.,

REGISTRATION.

“Architect, Surveyor, Auctioneer, and House, Estate, and Commission Agent, begs to announce that his attention is given to the Preparation of Plans, Specifications, &c., for the erection of New Buildings, Alterations, Drainage, &c. The development of Estates for Building Purposes, Valuations, Inventories, Delapidations. Sales by Auction, and otherwise, of Estates, Residences, and Properties of every description, the Letting of Furnished and Unfurnished Houses, &c. N.B.—Choice sites for Business and other Premises for Sale on the Brookfield, Ballastowell, and Mooragh Estates, and in other eligible parts of the town of . . . New Houses and Shops now in course of erection to be Let . . . It pays to advertise in this journal.”

#### CARRIAGE PAVING.

SIR,—If your correspondent, “E. W. H.,” will refer to a back number of the BUILDING NEWS, he will find an illustration of some paving, which I have lately had laid in Wellington-street, Strand, at the corner of Russell-street.

Last year the Horse-Accident Prevention Society was formed. I, being a horse owner, and taking a great interest in the subject, attended all their meetings, and I think they came to the conclusion that wood was the only form of paving in which the much-needed improvement could be made for the following reasons:—

1st. Wood does not jar a horse so much as other paving, and there is not the shock to the system in case of a fall. All must admit that the

London horses of the present time are far straighter in the legs than they used to be.

2nd. It is the most noiseless form of paving.

3rd. It is not so slippery as asphalt, and does not require the repair that macadam does.

Most of the London drivers will tell you that they prefer driving over the old granite cubes, as the horses are less liable to slip on them; but this paving is, I think, out of the question, on account of the tremendous noise. Seeing that the public were indebted to an architect for the invention of the hansom cab, and, judging from the protected (?) state of the profession, it is likely that most of its junior members will soon be driving these useful vehicles, I thought it would not be out of place, as a member of the profession, to turn my attention to the improvement of the roads over which they travelled.

With this object in view, I tried a number of experiments, finally deciding upon a form of wood paving, as laid in the street mentioned above, and similar in every respect to that suggested by “E. W. H.” in stone. The rounded arris prevents slipping, giving a foothold to the horse; in the case of a heavy load, it is something to draw against.

All horses stop themselves and start a load on their toes; proof of this is seen where the omnibuses pull up at the bottom of Fleet-street, the paving there being practically worn into the same section as mine.

The grooves run parallel across the road; they are not wide enough to cause any jolting with an ordinary-sized wheel, and they also act as a drain. I lay with asphalt, and then grout in, as suggested by “E. W. H.” The groove will last a 3in. wear of the block, and as the paving wears down the grouting wears out with it, thus preserving the foothold.

The wood is properly hardened, so that the corners do not spread or splinter. In my opinion, most of the faulty wood paving has been through laying the wood soft and in its green state, simply grouting it in. This form may be a little cheaper, but the system must be wrong.

Well-prepared wood paving has been known to last seven or eight years. Indiarubber will, I believe, be found far too costly, and the plain Jarrah wood too slippery.

After many endeavours to obtain permission for a trial, I was at last, by the kindness of the Strand Vestry, allowed to lay 40ft. at my own expense in Wellington-street. But, before this, it had been tried for some months, under heavy traffic, with most satisfactory results in the suburbs.

Had I been able to afford it, I would have laid the whole street, as 40ft. is not sufficient for a fair trial, a horse being no sooner on than off, before he can realise the change.

It also appears too little to have attracted much observation; this must be my excuse for again bringing the matter before those interested in it.—I am, &c., W. A. WILLIAMS, A.R.I.B.A.  
156, Regent-street, W.

A deputation from the Royal Institute of Architects of Ireland waited upon Lord Zetland, the new Lord-Lieutenant of Ireland, on Monday, to present a loyal address of welcome, signed by Mr. Thomas Drew, as president, and Mr. Albert E. Murray as secretary. In his reply, the Lord-Lieutenant referred to the new Science and Art Museum in Dublin, now approaching completion, as an example of the excellent work carried out by Irish architects, adding:—“In my visit to the building I was specially struck by the beauty of the Irish marble that decorates its walls, for I had no idea that this country could produce such varied and splendid specimens, which compare most favourably with Italy’s celebrated marbles. I do not doubt that if their excellence were more widely known, an important industry might soon be developed.”

An addition to the stained glass of Truro Cathedral has recently been made. The three lancet windows in the baptistry have been filled in memory of Mrs. Boger. The subject illustrates the life and work of St. John the Baptist. In the centre light is a figure of the Baptist; on the other two lights are Elijah and Noah, both preachers of repentance. In the lower compartments are placed the following scenes:—(1) The appearance of Gabriel to Zacharias; (2) the naming of the child; (3) the preaching in the wilderness; (4) the baptism of our Saviour; (5) Herod rebuked; and (6) the Baptist beheaded.

Lieut.-Col. William Wigginton, formerly a F.R.I.B.A., died on the 8th inst., at his residence at Forest Hill, in the 64th year of his age.

## Intercommunication.

### QUESTIONS.

[10205.]—**Surrey Churches.**—Will some correspondent who is acquainted with Oxted and Lingfield Churches, Surrey, kindly tell me if the same are worthy of being studied and measured, with a view of gaining a knowledge of style, ornament, mouldings, &c.; and also if there are other buildings within a few miles of above worth visiting, and their chief points of interest? Any information will greatly oblige.—VINCENT VENTAS.

[10206.]—**Strains.**—Will any reader tell me how to work out the following formula for strains—

$$C \frac{b d^2}{l} = W$$

C = constant

b = breadth

d = depth

l = length of bearing

W = weight.

It is for the following: weight 15cwt. in centre on a timber beam, 20ft. bearing. What is size of beam? I cannot, in working out by algebra, separate b and d.—Como.

[10207.]—**Bridges with Skew Arches.**—I shall be glad if any reader will give me any information as to the building of bridges with skew arches, or would name any books which treat this subject, not in a scientific way, but in one that a practical man could build from.—J. M’L.

[10208.]—**Perspective.**—Being engaged in a country office, and anxious to learn architectural perspective, I will be obliged if someone will advise me of the best book to obtain in order to teach myself.—DILIGENT.

[10209.]—**Sugar in Mortar.**—I should be glad to hear from any of your numerous readers whether they have tried sugar in mortar, and in what proportions? In 1886 some correspondence took place regarding the Indian practice, but no definite proportions were stated, except for plastering. I am now trying a series of experiments, and should be glad to know what others have done before, and the proportions, with results. I may say that there appears to be a very great increase in hardness of mortar, also quicker-setting properties imparted by the sugar. I am using the common Madras sugar.—JOHN CLARKE.

[10210.]—**Ventilation.**—Will some reader give the names of a few books on Ventilation, and which are considered the best on the subject?—M.

[10211.]—**Party Wall.**—A. wishes to rebuild his premises; but on preparing the plans it is found that adjoining owner B. has encroached on A.’s moiety of the party-wall with a plaster to the extent of 7in. A. wishes to put in a shop-front, and the frontage being narrow 7in. is a consideration. Can he compel B. to remove his plaster, notwithstanding that B.’s front is about 25 years old?—YOUNG PROVINCIAL.

### REPLIES.

[10175.]—**Buttress.**—The apparent discrepancy which “J. W.” finds between theory and practice as regards the thrust of a collar roof, arises from not taking into consideration the resistance of the rafter to bending. If the rafter is perfectly rigid, and does not bend at D where the collar is fastened to the rafter, it is evident that there can be no outward thrust on the support at B (see Fig. 7, p. 692, BUILDING NEWS for Nov. 22, 1889); and even if not perfectly rigid it may offer sufficient resistance to bending to counteract a part of the thrust, while the weight of the wall does the rest. This can be determined by the usual rules for strength of beams. Prof. Fenwick shows in “The Mechanics of Construction” that when the load is uniformly distributed over the rafter, the horizontal thrust at A is,  $H = \frac{1}{2} p (l + l_1)$ , cot.  $\alpha$ , where p is the load per unit of length of the rafter, l the length AB of the rafter,  $l_1$  that of the part AD,  $\alpha$  the angle of pitch. When  $\alpha$  is 45°, then cot.  $\alpha = 1$ . Consequently the value of H gets less and less as we diminish  $l_1$ , or as the collar is moved up towards the vertex A, and greater as it moves downwards towards B. When the point D reaches A, or there is no collar, H = half the load on the rafter; when the collar is half-way up the rafter H is three-fourths of the load on the rafter; and when D is at B, or the collar becomes a tie-beam, then H = the whole load on the rafter; the angle of pitch being 45°. Colonel Wray, R.E., in “Application of Theory to the Practice of Construction,” makes the following remarks on this kind of roof, the span of which, he says, should never exceed 18ft.:—“The ordinary position of the collar is half-way up the rafter, it being intended to act as a support to the middle of the rafter as well as to carry the ceiling. So long as the wall does not yield to the thrust, it actually performs this duty; but if the wall yields, the collar is brought into tension, and the rafter, in addition to being deflected by the distributed load, is further deflected by the tension of the collar applied at the centre of its length. The result is that the roof gets out of shape.”—E. W. T.

[10199.]—**Fireproof Floor.**—“Bray” does not give the least idea of the area to be covered, so that I cannot give the depth of joists, but suggest rolled joists and Portland cement concrete, from 6in. to 9in. thick. Form rough centring with boards on the underside of joists, and fill in from above.—H. L.

[10199.]—**Fireproof Floor.**—Try Blanchard’s blocks, which are of terracotta, and can be rendered thoroughly fireproof. By these blocks, which are grooved into rolled iron joists, and protect the flanges both top and bottom, the head room required is very small. The iron is protected from the action of the fire.—G. H. G.

[10201.]—**Damage.**—B. is liable to A. for reinstating the wall. If A.’s chimney was supported on B.’s wall, and B. takes down his house he is still liable to A. for its support. From the facts stated B. can be called upon to rebuild A.’s wall.—G. H. G.

[10201.]—**Damage.**—“J.” does not state whether the houses in question are in the county of London, or where, so that I cannot give an answer in accordance with

the Building Act, 1855. If in the provinces, the wall having been used for so many years as a party-wall, B. has no business to pull down to the injury of A., without arranging to make good to the wall in such a way that A. may not sustain injury. A. should consult a surveyor, who could inspect the premises and advise.—H. LOVEBROVE.

[10203.]—**Bridge Construction.**—The treatises by Haskell and Humber are good treatises on the respective kinds of bridge—masonry and iron.—G. H. G.

[10203.]—**Bridge Construction.**—**Heating.**—For the former, study Humber's great work (Crosby Lockwood and Co.); also "Modern Engineering," by the same author and publishers, both excellent, but expensive books. For heating, read "Warming and Ventilation," Weale's series, and get particulars from Messrs. Perkins, Messrs. Bacon, Mr. Grundy, and others.—H. L.

[10203.]—**Books on Hot-Water Heating.**—The best works on heating are Baldwin's "Hot-Water Heating," Hood's "Hot-Water Heating," and Billing's "Heating and Ventilation."—B.

[10204.]—**Crushing Weight of Stone.**—I have found Monk's Park a very excellent stone, uniform in colour, even, and close in texture. Ancaster is harder and heavier by about 15lb. per cubic foot.—H. L.

[10204.]—**Crushing Weight of Stone.**—The Commissioners on Stone for Houses of Parliament give 1'04 crushing weight of Ancaster (free-stone), 3'01 ditto for Ancaster (rag), 0'66 ditto for Bath (Box). This was tested in 2in. cubes, and no doubt on its natural bed. Although Monk's Park is not given, it is a similar stone to Bath.—J. W.

### LEGAL INTELLIGENCE.

**SUPPORT OF ADJOINING BUILDINGS.**—MILLER V. LONG.—An action was heard in the Queen's Bench Division, on Friday, brought by a cabinet-maker, of Shoreditch, leasing a house in Kingsland-road, against the executors of the owners of adjoining property, to recover damages, estimated at £101, arising from excavations which caused a wall of his workshop to fall, so as to interfere with his business and make it necessary for his family to remove for a time from the dwelling. The defendants paid £25 into Court, admitting that the excavations caused the wall to fall, but denying that the plaintiff incurred loss and expense necessarily to the extent alleged. Mr. Justice Mathew gave the plaintiff judgment for £40, including the sum paid into Court, with costs.

**IN RE BISSETT BROTHERS.**—The Official Receiver of Sheffield has issued a statement of affairs in the bankruptcy of Messrs. J. F. Bissett, L. C. Bissett, and W. C. Bissett, of Sheffield and Birmingham, builders and contractors, and who have carried out work in London, Brighton, Liverpool, and elsewhere. The unsecured creditors are put down at £34,439, and the assets at £6,758. Nothing reliable has been heard of the brothers W. C. and L. C. since they left the country.

### CHIPS.

The local board of health of Malton accepted at their last meeting the resignation of office sent in by Mr. C. W. Smithson, their surveyor and inspector of nuisances, who had been suspended from duty, and resolved to appoint a successor on the 22nd inst.

The death occurred on Wednesday week of Mr. Edward Ellis, of Fenchurch-street, at his residence, Bruce-grove, Tottenham, in his 73rd year. For 45 years he carried on a practice as an architect, during the last ten years of which he was in partnership with his son, Mr. E. B. Ellis, A.R.I.B.A. He had carried out the erection of many large buildings.

The Prince of Wales has consented to lay the foundation stone of the new vestry-hall and the public library buildings, for the vestry of St. Martin's-in-the-Fields, in the second week of March next.

A gift has been presented to Christ Church, Ealing, consisting of a font cover in oak and walnut, given by a member of the congregation in memory of an infant daughter. The design is pyramidal in outline, and the detail is Decorated Gothic in character, thus harmonising with the style of the church itself. The work was from the designs of Mr. Robert Willey, of Ludgate-hill and Ealing.

The Sphincter Grip Armoured Hose Company, limited, 9, Moorfields, have been awarded a bronze medal (being the highest award given for hose exhibited) for their patent Sphincter Grip Armoured hose, at the Brighton and Hove International Exhibition. The company have added five new patented improvements to their machinery since they first placed this hose on the market. The hose is now in very extensive use at the various departments of H.M. Government, the Continental and Colonial Governments, railway, steamship, and lock companies, the large engineering and other industrial establishments in this country and the colonies.

At a meeting of the governors of the East Retford Grammar School, the plans and specifications prepared by the Borough Surveyor (Mr. J. D. Kennedy) were presented and approved, and it was decided to advertise for tenders.

### WATER SUPPLY AND SANITARY MATTERS.

**LEAD POISONING FROM DRINKING WATER.**—At the last meeting of the West Riding County Council, a report was received from the Medical Officer of Health upon cases of lead poisoning which have occurred at Mirfield and other parts of the Riding. From time to time, for several years past, cases of lead poisoning have been reported in certain districts in the West Riding which are supplied with soft moorland water, and chemical analysis has shown that the water had become contaminated with lead in its passage through leaden service pipes. Why the contamination should be intermittent, and why it should be limited to certain localities, while others apparently similar remain unaffected, are points only imperfectly understood. Keighley, Batley, and the districts near Huddersfield and Bradford, have suffered considerably from this cause, and cases of lead poisoning have been especially numerous and severe in Mirfield, Batley, and Gildersome. All danger may be avoided by the use of iron pipes, or pipes of other materials, but even in new houses no substitute is so convenient as lead, and where lead pipes are already in use, the change involves considerable cost. Attempts have been made to prevent the solvent action by adding quicklime to the water, by running the water through conduits lined with limestone, and by adding silica. These remedies have never been thoroughly tested; nor, on the other hand, have the partial experiments always yielded satisfactory results, although at Keighley the water is still being treated with quicklime and exposure to limestone. Unless some means can be found of preventing the danger of soft waters acting upon lead, it will be essential for the public safety to prohibit the use of lead pipes for drinking water. If such a remedy can be found, its immediate adoption by the water-supply authorities is no less essential. It was resolved to urge the Local Government Board to direct an immediate and comprehensive inquiry into the matter.

**LONDON SEWAGE DISPOSAL.**—A discussion took place at the Society of Arts, Sir Henry Roscoe, M.P., presiding, on a paper recently read by Sir Robert Rawlinson, late Chief Engineering Inspector of the Local Government Board, regarding the London County Council's heritage of difficulties from the late Metropolitan Board of Works in respect to London sewage and sewerage. A long letter was read from Edwin Chadwick, K.C.B., the veteran sanitarian, dealing with some of the details of Sir R. Rawlinson's paper, and also a letter from Mr. John Phillips, the engineer to the old Board of Health, dealing with the separation of the sewage and the rainfall. In opening the discussion, Mr. Clare Sewell Read spoke on the question of applying sewage to the land, and doubted, seeing the cheapness of chemical fertilisers, whether it would pay the farmer to use the sewage. He himself had used dried sewage, but it had not done the land any good. Mr. Sillar advocated his own system of utilisation of sewage, by which the sewage is treated with chemicals and the effluent water run off, the rest of the solidified matter being known as "native guano." Dr. Dupré declared against sewage farms, and asserted the Metropolitan Board's deodorisation scheme had lessened the amount of the polluting effect of the sewage emptied into the Thames from that of 5,000,000 people to that of 2,000,000 people. Dr. Thudichum declared that the idea of applying London sewage to a farm was perfectly chimerical. Professor Corfield held that the question, first, was how to remove the nuisance of London sewage from the Thames, and how to make the refuse profitable was a secondary consideration. If the London County Council purified the Thames, that body would justify its existence. Mr. Isaac Shone, C.E., said that the London County Council would have to provide for the disposal of the sewage of 7,000,000 in a few years. Mr. James Lemon, C.E., insisted that trial should be given to the proposals to utilise the system at the outfalls. Sir Robert Rawlinson, in reply, repeated that all who had tried to make a commercial value of the sewage had failed.

The town council of Hyde, near Manchester, adopted on Monday a report by a sub-committee recommending that a scheme of sewage disposal be carried out on the plan in use at Acton, which is one of intermittent precipitation and filtration. The precipitant used is magnetic ferrous carbon—ferrozone—and the filter-beds are composed of layers of sand, gravel, and polarite. The sludge from the precipitating tanks gravitates in a liquid form into a well, and is then raised by pumps and forced through a series of presses, which reduce it to one-fifth its bulk, after which it is dried and sold for manure. The area which the proposed works will have to provide for is 3,042 acres, and the estimated cost is £12,500.

The parish church of Braunston, near Oakham, is about to be restored from plans by and under the supervision of Mr. J. C. Traylen, of Stamford.

### Our Office Table.

The foolish mistake made by the Secretary of the Institute on Monday when reading one of the prize winners' sealed letters caused considerable laughter at the time; but the actual fun of the thing clearly was not seen by the meeting. "*Margravine-gardens, Hammersmith*," was read out instead of the well-known "*Margravine-gardens*," which stand near the site of the once famous Brandenburg House, originally built by Sir Nicholas Crispe in the days of Charles I., at a cost of £23,000. Here Fairfax made his headquarters in 1647, and on the death of Crispe, Prince Rupert gave the place to his mistress, Mag Hughes, the actress, "a pretty woman newly come, called Pegg." Lord Melcombe bought the property, and altered it, adding a sculpture gallery, as figured in the "*Vitruvius Britannicus*." Mrs. Sturt afterwards made the house gay again, and turned Doddington's "Convent" into a rendezvous for royalty, and here it was that George IV., dressed as a Highlander, "made a lady feel his bare knee" (Sir Gilbert Elliott to Lady Elliott, June 13, 1789). All this the Secretary of the Institute was, of course, not supposed to know; but he ought to have remembered about the Margravine of Brandenburg-Anspach having lived so grandly at Hammersmith, and of the theatre there for the entertainment of the world of fashion, including the celebrated Duchess of Gordon and her three famous beauties, as well as the Countess of Cork. Here, too, Queen Caroline lived pending her trial in 1820. The mansion was then again the scene of constant turmoil, and the unhappy Queen died there two years later—

"All kinds of addresses  
From collars of SS  
To vendors of cresces  
Came up like a fair;  
And all through September,  
October, November,  
And down to December  
They hunted this hare."

Fulham Workhouse now stands on part of the grounds, and a private lunatic asylum till lately stood there. This account records only well-known events, and Margravine-gardens, too, has a history; not "*Margravine*," a word diverted from its legitimate meaning a few years ago, and degraded by being compelled to do duty for a better substitute.

MR. H. PERCY BOULNOIS, M.Inst.C.E., of Portsmouth, has been elected city engineer to the Liverpool Corporation in succession to Mr. Clement Dunscombe, now engineer-in-chief to the London County Council. Mr. Boulnois, who comes of a Huguenot family, is 42 years of age, having been born in 1847. He was educated at King's College, London, and was articled to Sir Joseph W. Bazalgette, C.B., with whom he was subsequently engaged in the construction of railways. He then proceeded to Jamaica, where he held a Government appointment for two years. The climate not agreeing with him, he returned to England in 1873, and was appointed city engineer of Exeter, a position he filled for ten years. He then became connected with Portsmouth as borough engineer, and has given a service of six years to that town. At Portsmouth he has carried out many works, including miles of new sewers and the canoe lake at Southsea. He is a Fellow of the Sanitary Institute, and is well known as a lecturer on sanitary subjects at the Parkes Museum, London, and various literary and scientific gatherings.

THE Yorkshire County Committee have under consideration a scheme for taking down the portion of the high wall surrounding York Castle, which abuts on Tower-street, and erecting in its place a dwarf wall of masonry with iron palisading. The cost of the change, which will open up a view of Clifford's Tower to the citizens, is estimated at £700, while the value of the Bramley Fall stone of which the wall consists is set down at £900, so that the operation will be almost costless. The wall, only a portion of which it is proposed to interfere with, has no antiquity to protect it from removal, for it was only erected in 1825-37 by order of the county committee; the outlay was no less than £203,530, and was met by an annual rate of 1½d. in the pound during the twelve years the alterations were in progress.

MR. LAWSON TAIT, the well-known surgeon, writes stating that, while in an old curiosity

shop at Birmingham, he found two church brasses, belonging, he believes, to the end of the 15th century, and clearly of the same make. They seem to be a pair, belonging to one slab, from which they have been violently wrenched from their matrix. They are about 22in. long, and at the broadest part of the body 6in. across, and both of the figures are females, in all probability the two wives of the major feature of the group, as one turns to the left and the other to the right. Mr. Tait offers to make the brasses over as a gift to any clergyman who can prove that they belong to his church, and for the purpose of identification he will either send rubbings or visit the spot, from which similar memorials are missing, with the brasses. He suspects that they have been taken from some church in Oxfordshire, Berkshire, or North Hampshire.

The Corporation of Newcastle-on-Tyne have under consideration a scheme submitted by a special committee for the alteration and practical reconstruction of the town-hall, concert-hall, and municipal offices, now quite inadequate to the requirements of the city, at an estimated cost of £46,000. Some opposition is offered to the proposal by certain public-spirited citizens, who point out that as tinkered up the buildings are not expected to be equal to the needs of Newcastle for more than a quarter of a century, and that truer economy would be displayed by demolishing the whole block, and erecting on its site and over adjoining business premises, a modern and commodious suite of offices worthy of the city, and creditable to its reputation.

Mr. J. G. BROWN, the assistant surveyor under the Sunderland Corporation, died at his residence in Peel-street, Bishopwearmouth, on Friday. The deceased, who had been for many months past incapacitated from following his occupation, owing to a painful malady, was a man of cultured tastes and literary ability, many of his contributions appearing regularly in the local newspapers. He was best known for his biographies of local characters, and descriptions of well-known North Country scenes, the sketches of which were greatly enhanced by the illustrations of his son, Mr. J. Gillis Brown. Mr. Brown himself was an artist of some ability, and his literary work was not only interesting but of historical value. He was born in Newcastle, but had been a resident in Sunderland for nearly forty years. His first appointment in Sunderland was as assistant engineer to Mr. Meek, the engineer to the Wear Commissioners. He was afterwards connected with the architect's department of the N.E.R. Company, and subsequently held the appointment of bridge master for the North Riding of Yorkshire. Until within the last few months he had discharged the duties of his office in Sunderland, which he had held for fifteen years.

#### CHIPS.

At Thursday's meeting of the London School Board Mr. James Taylor, Mr. Joseph Taylor, Mr. T. E. Wilford, and Mr. T. Woodhouse were appointed additional clerks of work for repairs at the commencing salary, under the scale, of £150 per annum; and Mr. C. Frost was also appointed clerk of the works for repairs (vice Mr. W. J. Cooper, deceased), at the same commencing salary.

An anonymous correspondent offers £1,000 as the nucleus of a fund for placing on the vacant pedestal in Trafalgar-square a replica of Boehm's equestrian statue at Calcutta of the late Field Marshal Lord Napier of Magdala.

Mr. John Eaglesham, C.E., Ayr, was appointed on Monday surveyor for Ayr burgh at a salary of £250. He is to give his whole time to the duties of his office.

A new organ chamber at the parish church, Alnwick, was dedicated on the 15th inst. The chamber measures 18ft. wide by 20ft. long, and 22ft. high, and is placed on the north side of the ancient chancel, and recedes under a fine arch in keeping with the Perpendicular character of the fabric. The contractor was Mr. Wm. Darling, Alnwick, and the architect was Mr. Fred. E. Wilson, Alnwick, diocesan surveyor.

The London County Council, at their meeting on Tuesday, decided to appropriate the vacant space in the centre of Piccadilly-circus for the fountain to be erected as a memorial of the seventh Earl Shaftesbury. The fountain has been modelled by Mr. Alfred Gilbert, A.R.A., and will have a height of 30ft.; it will be octagonal on plan, and have a frontage of 23ft. on each face.

#### MEETINGS FOR THE ENSUING WEEK.

**MONDAY.**—Royal Academy. Lecture on "Painting," No. 6, by Prof. J. E. Hodgson, R.A. 8 p.m.  
Royal Institute of British Architects. Award of Prizes and Address by the President, A. Waterhouse, R.A.  
Society of Arts. "The Electro-Magnet," No. 1, by Silvanus P. Thompson, D.Sc. 8 p.m.  
Leeds and Yorkshire Architectural Society. "Public Libraries," by E. W. Mountford. 7.30 p.m.  
**TUESDAY.**—Institution of Civil Engineers. Discussion on "Recent Dock Extensions at Liverpool." 8 p.m.  
Society of Arts. "Tea, Coffee, and Cocoa Industries of Ceylon," by J. L. Shand. 8 p.m.  
Manchester Architectural Association. "Perspective: a 30th-Century Architect," by F. R. L. Edwards.  
Glasgow Architectural Association. "Decorations," by A. Roche.  
**WEDNESDAY.**—Society of Arts. "Vision Testing for Practical Purposes," by R. Brudenel Carter. 8 p.m.  
**THURSDAY.**—Royal Institution. "Sculpture in Relation to the Age," by E. R. Mullins. 8 p.m.  
Royal Academy. Lecture on "Painting," No. 6, by Prof. J. E. Hodgson, R.A. 8 p.m.  
**FRIDAY.**—Institution of Civil Engineers. "The Up-Keep of Metal Roads in Ceylon," by T. H. Chapman. 7.30 p.m.  
Royal Institution. "The Scientific Work of Prof. Joule," by Prof. Dewar. 9 p.m.

Among the adjudications in bankruptcy announced in Tuesday's *London Gazette*, the name occurs of William Youlten, late of James-street, Bedford-row, now of Finsbury-square, E.C., architect and surveyor.

St. Saviour's Church, Upper Chelsea, is about to be enlarged at a cost of £3,000. Messrs. Geldart and Randall-Vining are the architects, and Messrs. Foster and Dicksee, of Rugby, are the builders.

A new county hall has been erected at Anglesey, and special attention has been paid to the ventilation, the latest improved form of Messrs. Robert Boyle and Son's patent Self-Acting Air-Pump Ventilator being adopted for the extraction of the vitiated air.

A series of buildings for use as test houses have just been erected for the West Derby board of guardians in Belmont-road, in that township. They form a range of seven large pavilions, each building being about 400ft. in length. Mr. C. H. Lancaster, of Liverpool, was the architect.

**Holloway's Pills.**—The balsamic nature of Holloway's Pills commends them to the favour of debilitated and nervous constitutions, which they soon resuscitate. They dislodge all obstructions, both in the bowels and elsewhere, and are, on that account, much sought after for promoting regularity of action in young females and delicate persons.

#### DOULTING FREESTONE.

**THE CHELYNCH STONE.**—The Stone from these Quarries is known as the "Weather Beds," and is of a very crystalline nature, and undoubtedly one of the most durable Stones in England.

**THE BRAMBLE DITCH STONE** is of the same crystalline nature as the Chelynych Stone, but finer in texture and more suitable for fine moulded work.

Prices, and every information given, on application to CHARLES TRASK and SONS, Doulting, Shepton Mallet, Somerset. London Agent:—Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.

#### HAM HILL STONE.

The attention of Architects is specially invited to the Durability and beautiful Colour of this material. Quarries Well Opened; Quick Despatch Guaranteed; Stonework Delivered and Fixed Complete. Samples and Estimates Free.

Address:—**THE HAM HILL STONE COMPANY,** NORTON, STOKE-UNDER-HAM, SOMERSET. London Agent:—Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.C.

#### ELECTRIC LIGHTING.

**COMPLETE INSTALLATIONS OR WIRING ONLY** ESTIMATES GIVEN.

**STRODE & CO.** 48, Oldbrough-st., N.W., and 67, St. Paul's Churchyard, E.C. New Branch Showrooms:—188, PICCADILLY, W. Telephone No. 3958.

**WM. OLIVER & SONS,** MAHOGANY, WAINSCOT, WALNUT, TEAK, VENEER, and FANCIWOOD MERCHANTS,

120, BUNHILL ROW, LONDON, E.C. The most extensive Stock of every kind of Wood in Planks and Boards, dry and fit for immediate use.

#### TENDERS.

\* \* Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender: it adds to the value of the information.

**AUDENSHAW.**—For sewerage, levelling, kerbing, flagging, and paving Paradise-street, Providence-street, Mount Pleasant-street from Manor-street to Providence-street, and Manor-street; also levelling, kerbing, flagging, and paving only Mount Pleasant-street from Tame-street to Manor-street, for the Audenshaw Local Board. Mr. J. H. Burton, Ashton-under-Lyne, surveyor:—  
Underwood & Bros., contractors, Dukinfield, per schedule of prices.

**AUDENSHAW.**—For sewerage, levelling, kerbing, flagging, and paving Lord-street, for the Audenshaw Local Board. Mr. J. H. Burton, Ashton-under-Lyne, surveyor:—  
Worthington and Pownall, contractors, Manchester, per schedule of prices.

**BARMOUTH.**—For extension of cast-iron outfall sewer. Mr. T. Roberts, A.M.I.C.E., engineer:—  
Williams, E., Bangor ... £2,980 0 0  
Griffiths, G., Criccieth ... 2,965 0 0  
Morris, O., Carnarvon ... 2,855 0 0  
Williams, A., Aberdovey ... 2,400 0 0  
Engineer's estimate, £2,439.  
\* Accepted.

**BECKENHAM, KENT.**—For the erection of a residence, for Mr. G. H. Manger. Mr. G. W. Cooper, Bedford-row House, Bedford-row, W.C., architect. Quantities by Mr. A. R. Brede, Bedford-row House, W.C.:—

Billiard-room.	Palmer, E. R., Beckenham	£1,670 0 0	£200 0 0
Graham and Co., Beckenham	1,650 0 0	198 10 0	
Mid Kent Building Works,	Beckenham	1,600 0 0	200 0 0
Mattock Bros., London	1,537 0 0	193 0 0	
Patman and Fotheringham,	London	1,585 0 0	220 0 0
Jerrard, S. J., Lewisham	1,533 0 0	193 0 0	
Price, C. W., Beckenham	1,440 0 0	175 0 0	

**BIRKENHEAD.**—For the erection of a weights and measure office, for the town council:—  
Davies, R. (accepted) ... £270 0 0

**BODMIN.**—For laying a causeway in Gaol-lane, for the town council:—  
Harris, E. (accepted).

**BOOTLE.**—Tenders for the erection of the new police buildings at Bootle. Mr. C. J. Anderson, Liverpool, architect. (Illustrated in *Building News*, Oct. 25, 1889.) Architect's estimate, £8,400. Twenty tenders received:—

Wood, G., and Son, Bootle	£11,678 0 0
---------------------------	-------------

\* This was the lowest tender, and at the town council meeting on Wednesday, after some discussion on the discrepancy between the estimated cost of the buildings and the amount of the lowest tender, it was decided to accept Messrs. Geo. Woods and Son's tender, and to borrow £12,000 to defray the cost of the building.

**CADOXTON.**—For the erection of 12 houses in Moor-road, for Mr. J. Morgan. Messrs. Richards and Gethin, architects:—  
Mathews Bros., Cadoxton (accepted) ... £1,800

**CADOXTON.**—For forming Old Mill-road, Cadoxton, for the Wenroe Castle estate. Messrs. Richards and Gethin, surveyors:—  
Roberts Bros., Cadoxton (accepted).

**CADOXTON.**—For forming Belle Vue-road, Cadoxton, for Mr. Chappell. Messrs. Richards and Gethin, surveyors:—  
Brock, J., Barry (accepted) ... £450 0 0

**CAMBRIDGE.**—For new premises at the corner of the Market-hill and Petty Cury, Cambridge, for Mr. W. Bond, J.P. Mr. G. McDonnell, F.R.I.B.A., Barnsbury, London, architect. Quantities by Mr. J. Yarrow, 16, Milford-street, Cambridge, surveyor:—

Prime	£5,020 0 0
Bell and Sons	4,574 0 0
Willmott and Sons (accepted)	4,225 0 0

(To be completed by 30 Sept., 1890.)  
All of Cambridge.

**CARDIFF.**—For the erection of trimmers' lodge, Barry Dock, for Messrs. Worms, Josse, and Co. Messrs. Richards and Gethin, architects:—  
Milward and Co., Barry (accepted).

**CARDIFF.**—For the erection of 94 cottages in Sydenham and Fryatt-street, Barry Dock, for Mr. J. Milward. Messrs. Richards and Gethin, architects:—  
Smith, R., Cardiff ... £16,030 0 0  
Valis, P., Cardiff ... 15,400 10 0  
Edmunds, J. C., Penarth ... 15,000 0 0

**CARDIFF.**—For the erection of 42 cottages in Lombard-street, Barry, for Messrs. Jenkins and Rees. Messrs. Richards and Gethin, architects:—  
Edmunds, J. C., Penarth (accepted) £4,953 0 0

**CARDIFF.**—For making Burlington-street, Barry Dock, for Messrs. Jones and Roberts and J. James. Messrs. Richards and Gethin, surveyors:—  
Brock, J., ... £485 5 8  
Smith, R., Cardiff ... 410 0 0  
Love, D., ... 370 3 11  
Milward and Co. ... 365 6 9

Rest of Cadoxton.

**CARDIFF.**—For the erection of offices at Barry Dock, for Messrs. D. Davis and Sons. Messrs. Richards and Gethin, architects:—  
Jones Bros., Cardiff ... £310 0 0  
Price, R., Cardiff (accepted) ... 276 15 0

**CARDIFF.**—For the erection of three shops in Holton-road, Barry, for Mr. D. Jones. Messrs. Richards and Gethin, architects:—  
Ashite, G., Barry ... £2,041 0 0

**CARDIFF.**—For the erection of offices, Barry, for Messrs. D. Davies and Co. Messrs. Richards and Gethin, architects:—  
Price, R., Cardiff ... £248 15 0  
Jones Bros. (accepted) ... 240 0 0

FRIDAY, JANUARY 24, 1890.

## WHOLESALE CONTRACTS.

TO the eminently practical mind of the English employer of labour, a bargain by the lump has an attraction. It is a less troublesome and irksome mode of obtaining what he requires than in employing his own tradesmen to do the work at a fair measure and value price, and in taking upon himself the duties of the general contractor. Not only does he like to know the cost from the beginning, but he fancies that by dealing with separate tradesmen he will get himself involved in expense and difficulty, and it is this fear which deters so many building promoters from undertaking any work themselves. Public bodies, in whom the power rests of advertising for tenders, adopt the same course in what they deem the interests of those they represent; they obtain a tender for a public building, such as a vestry hall or a board school, which shall be inclusive of everything connected with it. As these tenders are generally based on competitive prices obtained in the open market, it is next to impossible that any margin can be left for remuneration. The recent School Board scandals are to be attributed mainly to the keen competition promoted; the highest and lowest tenders have shown a difference of several thousands of pounds, and as the lowest tender is generally accepted, the builder is compelled to have recourse to the "sweating system." The public have been the sufferers: they have had to pay for defective building at a higher price than they would have done if the highest tenders had been accepted, in addition to costs of actions in the courts for alleged libels.

The question of responsibility enters into this mode of contracting. By making the contractor responsible for all risks and defects, the idea of employers is that they get the best part of the bargain. But what are the facts? The majority of buildings carried out under contracts cost a considerable addition of percentage for extras, or are found so defective afterwards as to entail a heavy expenditure. Sometimes the contractor is unable to fulfil his engagement, and we have only to turn to the facts revealed in the London Board School proceedings to find cases of all three of these. A contractor's responsibility cannot be determined by the stringency with which the contract agreement has been drawn up, as many appear to imagine, but his obligations to carry out the work in a satisfactory manner will mainly depend on his position as a contractor, and will rest on the amount of his tender. Experience has proved that the measure of his responsibility is directly in proportion to the remunerativeness of the price he has agreed to work for. If we cut him down in price, he will be inclined to scamp the work, or to introduce inferior materials; and though compulsory measures may be taken, we shall find they are inoperative to produce satisfactory results, as any loophole will afford him relief. In the wholesale contract, as each trade works under handicapped conditions, the responsibility falls upon the contractor of the whole. Each sub-contractor agrees to do his portion of the work at the lowest cost, undertaking to carry out his particular trade in compliance with the terms of the specification. But sub-letting under the contractor fails, because the artisan knows that he is not directly answerable, and shelters himself under the contractor's responsibility. These conditions are inimical to good building. The profits of the artisans

are reduced to a minimum. The large contractor, who supplies his own materials as well as labour, and pays by time, can appropriate the profits and do the work cheaper; but the workman is reduced to a machine: he works in a groove, and a process of cheese-paring is exercised prejudicial to the building. Whether one wholesale contract, or several separate ones are better for the employer is a question that can be answered by comparing buildings erected under both systems. In France and Germany, and America, as well as in the North of England and Scotland, we find the separate system largely in operation. It will not be denied by the most strenuous supporters of wholesale contracts that the separate tender system is less open to scamping than the undivided contract. The objections to this plan is that it involves a series of separate agreements—entails more trouble on architect and surveyor. On the other hand, more careful workmanship and individual responsibility are secured, as each tradesman has an interest in turning out his particular portion of the work in such a manner as to give satisfaction, and as all the trades take the same individual responsibility and interest, there is more chance of obtaining good work than when one contractor only is interested. We do not say that if the wholesale contract is based on a just tender, and conducted with the necessary safeguards, it is not the most desirable plan of carrying out buildings; but we contend that with keen competition and the acceptance of tenders at unremunerative prices—which is generally the course now followed by our boards and public authorities—the system is most pernicious, and the employer is unquestionably the loser. Need we cast our eyes at some of the London Board Schools to see the result, to find almost every trade grossly scamped—to wit, the recent examinations of the superior officer of the Board, who has found out imperfect, and in some cases not any connection between, drains and the sewer-pipe, allowing the soil to percolate through the ground; in other instances, absence of ventilation of drains, some completely at variance with the plans of the architect.

The system of obtaining tenders is open to serious question. The above startling disclosures would never have been possible if the schedule system of obtaining quantities prevalent in Glasgow and other towns in the North had been adopted by the Board, by which system the selected tradesmen tender upon schedules which are returned to the architect with the rates filled in against each quantity, the work being afterwards measured and valued by the same rates. But, as we have hinted, this procedure is distasteful to the ordinary employer, and to those who prepare contracts and quantities; the former prefers to know the entire cost at the onset, the architect and quantity surveyor object to a system which would give them more labour, while the usual bill of quantities would be superseded by schedules, and the large emoluments made would be reduced. The wholesale contract based on a single tender and bill of quantities is the plan that has been most favourably considered by the employer, because it is less troublesome, and by the builder and architect because it reduces their labour; but it fails to secure either good workmanship or fairness to the contractor: further, the system has a tendency to ruin trades, and to encourage "slop" hands and jerry-builders. All details are neglected. Two alternatives remain: the one is to encourage separate contracts, to let the trades of a building out in parts under a competent clerk of works; the other is to adopt another method of tendering and contracting by which a fair value will be paid for good workmanship—the only alternative likely to reform the general contracting system as it at present exists. The "lump" sum contract, with its unadjustable pro-

visions for after settlement of extras and omissions, with arbitration clauses that are seldom resorted to, have encouraged not only bad building but jerry-builders. If our large public buildings, like schools, were carried out on either of these plans, we should never probably have heard half the complaints we do now about buildings which are erected by contract. Separate contracts, for example, might be entered into for the erection of the building: one contract for the carcass, another for the mason's work, another for the carpenter and joiner's work, and these would be under the strict supervision of a competent clerk of works. We doubt very much whether his labour in supervision would be so onerous as it is under the old system of one contractor and one foreman, with the everlasting production in case of dispute of a deficient bill of quantities, the constant endeavour of the foreman to introduce the wrong material or to evade the specification and drawings, the hard words exchanged between the two representatives, and the evil that, if friendship is again made, the building may suffer more than ever. Each separate contractor, for his own sake, would do his best, and the clerk of works would be more a master of the situation than he is now, when the contractor is often, owing to the low price at which he has taken the work, dictatorial, or is in a better position to plead for a more lenient interpretation of the quantities. The tendering for these separate contracts would be managed in the usual manner, any extras or variations being determined by a schedule of prices and measure and value. The employer would benefit by the division of the labour; but beyond this, the mere middleman would be supplanted, and encouragement be given to tradesmen who are now afraid to compete against the powerful contractor.

There is another aspect of the question which affects the architect—we mean the execution of details in building. One of the hardest duties of the architect in a large contract taken for a low amount is that of carrying out the details of his design. Every one who looks beyond his mere percentage is aware of the difficulty of obtaining attention to details from some contractors. They seem to think that, as they have taken the work at a low price, every consideration should be shown them, and that the architect ought to forego his details and fittings. His price has been given for the mass, and details are considered too trifling to discuss. It is in this spirit the ordinary contractor acts towards the architect and employer. If each trade was separately considered, a very marked change in this respect would take place, and architects and employers would then be able to introduce specialities into their buildings, which now they have neither power nor heart to ask for.

## SPORT AND ART EXHIBITION AT THE GROSVENOR GALLERY.

AS a collection of pictures, apart from the themes of some of the subjects represented—many of them painfully suggestive of the "killing something" propensity of Englishmen—the exhibition at the Grosvenor Gallery illustrative of sport is of much interest. One of the earliest pictures is lent by the Duke of Westminster—"A Hare" (55), alleged to be by Albert Dürer, though stated by Mr. W. M. Conway, late Professor of Fine Arts at Liverpool University College, to be an enlarged copy from one of the finest of Dürer's drawings at Vienna. However, it gives apparent evidence of the master by the minute detail in which every part of it is painted. Near this is a large picture lent by Lord Ashburton of "A Spanish Fête," dark in colouring and attributed to Velasquez; a landscape in which a long inclosure of screens is erected, in which spectators are

viewing some sport. "The Wolf Hunt" (32), a still older work, is said to be by Rubens. The canvas is of huge size, hangs in the centre of gallery, and contains wolves, dogs, and several figures, some on horseback, including the well-known portrait of the painter's wife and that of himself, executed with all the animation and brilliancy of colour of the master. It was painted in 1625. The other picture of Rubens (62) "Diana Returning from the Chase," in the centre of long wall, is lent by the Duke of Northumberland, and is full of glowing colour and poetic feeling. The goddess of hunting is shown with her usual attendants, clad in a scarlet short-skirted garment.

Of less historical value we must mention the "Perch Fisher" (3), by G. Morland—a stream under the foliage of trees, in which there is a warmth of colour; Landseer's clever "Study of Heads" (4), "Hunter and Hounds" (6), lent by Lord Cheylesmore. His touching and pathetic picture of "Highland Nurses" (8) is well known by the engraving, and represents an incident in the painter's own experience, where a wounded deer is attended by her young. "Highland Interior," "None but the Brave Deserve the Fair" (69), "Retriever and Woodcock," "Monarch of the Glen" (88), the last lent by Lord Cheylesmore, and the fine subject, "The Sanctuary" (67), lent by the Queen, are among the notable Landseers in this gallery. Altogether there are 54 examples of this painter's work. The "Monarch of the Glen" (88) is the now familiar picture, through the art of the engraver, of a stag perched on a precipice or rock—a grand composition, wonderfully true to life, the atmosphere and colour charmingly harmonious, and the coat of the stag splendidly realistic. This picture was painted for the refreshment-room of the House of Lords for 300 guineas. The House of Commons rejected the vote, and Lord Londesborough bought it for 800 guineas; the copyright was sold to Mr. Henry Graves for 500 guineas. Afterwards it was sold at Messrs. Christie's, to Lord Cheylesmore, for £6,000. Passing this picture, which stands at the end of the large room, the next one of interest is "The Connoisseurs" (115), with a portrait of the artist between two favourite dogs, who look over his shoulder. The painting is graceful and full of tender pathos, and now belongs to the Prince of Wales. In the other gallery is "The Shrew Tamed," known as "The Pretty Horsebreaker"—a loose-box with the young lady in riding habit reclining on the straw, leaning her head on the body of the tamed steed. Other Landseers can only be glanced at: such are "Children of the Mist," on which the painter received many congratulatory remarks; "The Stag at Bay," a chalk study on paper, a series of studies being shown in the East Gallery (121, 122, 125, &c.) "Honeymoon" has all the poetry and pathetic interest of the painter (184), while the "Morning" (186), a large picture of dead stags on the mountain side, is a noble and stirring incident. A huge pastel subject, "The Chase"—a fine stag and a hound trying to keep pace, is of interest, inasmuch as the nose of the deerhound, since added, covers the mark Landseer placed on the stag's side, to show the right place to strike a deer. "Browsing" (203), too, is a fine drawing of the "antlered stag" in its more peaceful moments. The Holme Wood collection is laid under contribution for many of these examples.

In the West Gallery we must note the work of J. N. Sartorius on "Pointers" (5), "Hunting" (22), "Death of the Fox," and other hunting and racing scenes (133), and portraits of famous racehorses. But the great horse painter is George Stubb, A.R.A., whose *forte* as a portraitist of racehorses and other animals is shown by such pictures as (47) portrait of "Molly Long-Legs"—a landscape, with jockey in blue jacket, hold-

ing a bay filly, whose career upon the turf was a brilliant but short one; (63) portraits of William, Duke of Portland, and Lord E. Bentinck, who are shown as figures in a landscape, with a black horse and a groom leading a cob to a leaping bar. In other instances we see the painter's skill in portraits of horses, such as the "Eclipse" (86), the sire of 334 winners, "Shark" (81), both pictures belonging to Mr. Walter Gilbey; "Mares and Foals" (97), lent by the Duke of Westminster, who is a large contributor. The last is a fine piece of horse-painting. Stubbs modelled his horse's limbs and flanks with extreme care; the drawing is true to life and graceful. No. 91, "Mambrino," a grey horse, the sire of Messenger, from which the best American trotters are descended, is a good instance. No. 60, the portrait of a gentleman on a grey horse, with the Old Riding School at Welbeck, is another fine specimen of Stubbs's work, showing his mastery of colour, accessories, and background. Carl Haag's "Evening at Balmoral" (28), the stalked stags brought home, with figures of the Queen, Prince Albert, Prince of Wales, Duchess of Kent, and others standing at the threshold of the Castle, is a finely-painted scene; the torchlight effect is skilfully rendered. It belongs to the Queen. So, too, does "A Stag Hunt" (29), by J. Wootton, another eminent painter of animals. The Earl of Carnarvon sends Sir Francis Grant's "Ascot Meet of Stag-hounds," on which picture (too technical and overcrowded) numerous huntsmen and celebrities figure (41); and we must also pay tribute to Hondecoeter's "Horses, Dogs, and Grooms" (30); his "St. Leger," 1812 (31), a large centre picture; to J. Janssen's "Dead Game," a small but finely-painted group (43); to Landseer's large painting, "The Swannery Invaded by Eagles" (68); to Morland's delicately-painted interior, "Innocence Alarmed" (73), with sportsman discharging lock of a flint gun, frightening a child, who clings to her mother; to Snyder's large "Wild Boar Hunt," and a warm-toned picture by Morland (83), also "Rabbiting" (76). The picture of St. Hubert, the patron saint of hunting, by Breughel (51); R. Wilson's interesting "Cricket Match at Hampton Wick," lent by the Marylebone Cricket Club; S. Gilpin's portrait (77); J. Weenix's "Dead Game" (108); Briton Riviere's "Vae Victis!" eagle and wolf in combat on a rocky eminence; and the portrait of R. Tattersall, the founder of Tattersall's (112), are other works of interest, and in this connection we must name Johann Zoffany's "Old Tattersall's" in 1776, whose site is now covered by Grosvenor-crescent.

In the East Gallery are hung several pictures of note. In addition to several Landseers noticed, we see Briton Riviere's "Wounded Adonis"; Herbert Johnson's "The Prince of Wales's" tiger-hunting exploit in India, 1876, lent by His Royal Highness (162); and a spirited water-colour sketch of Randolph Caldecott (178). Dendy Sadler has a charming picture (180) of "Lea Roachers," and "A Pegged-down Fishing Match" (195), full of humour and masterly delineation of character; and we find works by Jan Fyt (132), J. Bateman (138), H. Alken, Rosa Bonheur (166), Gainsborough (171), Herring (174), a finely-painted moor scene by A. Stuart Wortley (182)—a deliciously soft and mellow picture, full of tone, light, and shadow, "Old Friends," by W. Huggins (187), and J. C. Hook's clever "Fishing by Proxy" (188). In the third room are several portraits of racers by J. F. Herring, winners of the Derby and St. Leger; also pictures of horses by S. Gilpin, R.A., Sartorius, Chalon, J. Seymour, and Wootton. A. Cooper, R.A., is represented by several pictures—duck shooting, pheasant shooting, partridge shooting (254-257), Stubbs's "Godolphin

Arabian," lent by the Duke of Leeds, and J. F. Herring's "Horses' Heads" (290), and J. Seymour's "Famous Carriage Match at Haymarket against Time, 1750," are historically of interest; so are the series of coaching pictures by Alken and Boughton's "First Journey of the Exeter and Devonport Coach," with a child's head inside, by Sir T. Lawrence, P.R.A.

We can only glance at the room given to the art of falconry, where we find pictures of fighting cocks and of stag-hunting, pheasant and grouse-shooting, fishing, and other sports; also a perch of hawks used by English falconers. A few works by Sir E. J. Boehm, R.A., R. Bonheur, Fremiet, and Jacquemart are amongst the sculpture. The fine collection of plate in the West and East Galleries, consisting of racing cups and plates, statuettes of horses, fowling pieces, a collection of arms and flasks will alone repay a visit. Thus we see the First Ascot Queen's Cup, 1839, a very beautiful and unique design after German 17th-century work; the Emperor of Russia's Ascot Cup (3), another Ascot Cup representing St. George and Dragon, lent by the Duke of Portland, who contributes several racing cups. Messrs. Hunt and Roskell and Messrs. Elkington and Co. also lend some notable specimens of cups and other silver articles. Great plate, representing Godfrey de Bouillon (24), lent by the Duchess of Montrose, is a conspicuous silver group in the cases, and was a prize given by the late King of the Netherlands. Some of the designs are unique, such as the New-castle Cup, 1824. The cases of arms comprise wheel-lock guns of the 17th century, a Couteau de Chasse of the French Empire, several beautiful powder-horns, a 16th-century combination axe and gun, crossbow belts, hunting knives, carved walnut flask of the 16th century, a "prod" or stone-bow for discharging pebbles or clay, used in Elizabethan times for fowling; a case of breech-loading repeating flint rifles and flint guns, many lent by the Duke of Devonshire, Prince of Wales, and Purdey and Sons. The entrance-hall is adorned, over the staircase, by a huge black Russian bear, lent by the Duke of Edinburgh. On the walls are trophies of bear-heads and antlers, black-tail heads of the genus *Cervus*, including one of a white-tail deer (112), with 60 points, from Southern Texas. Other spoils of the chase decorate the walls. Portraits of celebrated racers, stalked stags, hunting, racing scenes, foxes and foxhounds make up the bulk of this fine collection of sport. There is a little wearisomeness in an exhibition of this character. Some of the pictures suggest too vividly the cruel nature of sport, others display too much of the *technique* of sport, as in the "Spanish Fête" ascribed to Velasquez, and Sir F. Grant's elaborate picture of portraits of hunting notabilities, "The Ascot Meet of Her Majesty's Stag-hounds," where the scarlet coats, hunters and hounds are numerous and distracting, and we lose the artistic qualities in the composition. It and others of its class have an historical interest as a record, and it is only in the pictures of Rubens, Snyders, Morland, Gainsborough, Herring, Landseer, and one or two more that we can see the true painter's handling of sport.

#### ARCHITECTURAL BRICKWORK.— XXVII.

##### ARCHES.

IN brickwork considerable effect is obtained by the arch. Its construction being visible, care should be used in setting out the arch bricks, in making them radiate properly to their centre, and in cutting the bricks to the true bevel. A faulty brick arch reflects on the skill of the bricksetter, and detracts from the general appearance of the work. In our last article we described a

plain segmental arch formed with heading bricks, such as those generally seen over windows and doors. Each voussoir is a brick tapered to the required curvature; but, as we said, there are two other modes of constructing an arch, either as it is in Flemish or English bond. In both these cases the face of the arch presents alternately a single brick and two half-bricks—that is, every other voussoir is divided by a joint, which follows the curve.

#### ARCHES IN FLEMISH BOND.

We now show Fig. 1, a gauged arch over

2

an opening in Flemish bond. The bricks are alternately 9in. and 4½in. deep. This kind of arch is used for an opening, in which the reveals are 9in. deep, as then the intrados face or soffit would show the right bond, that is, a stretcher and header alternately. When the reveals are only 4½in. deep, the bricks of the arch are all 9in., as in our first example, and this is the only way an arch can be constructed over an opening in a wall of half a brick thick. An authority on arch building, Col. Pasley, says, speaking of the three methods, the Flemish bond, the English bond, and the heading bond previously described, "I am inclined to think the heading bond is the best of all, for the strength of an arch depends most upon the length of the voussoirs, which constitute its thickness; and in great arches, such as those of bridges, where stones are used, the voussoirs are all in one piece, not in several lengths or successive courses." By the "heading" bond arrangement it will be remembered is meant an arch on which all the bricks, except on the faces or extremities of the arch, are their whole length—a section of which will be represented by the arch, Fig. 1, page 61. For appearance in the fronts of houses, the Flemish bond arch, such as we now illustrate, is preferable.

#### STRAIGHT ARCHES.

The straight, or French arch, so commonly met with in old Queen Anne or Georgian houses, is certainly a sham construction at the best, as the horizontal joints, which usually cross the bricks, are all false, and marked for appearance on the bricks, the real joints being perpendicular to the radiating joints, and concealed. These straight arches are generally equal in height to four courses of the brickwork; but as the

arch bricks are on the slant an additional half-brick is put on, making the arch look 1½-brick thick. A horizontal joint is, therefore, introduced, as described, alternately in each voussoir to break bond. The straight, or camber arch has a rise of about ½in. for each foot of opening. One word of advice is necessary as to the working of bond above and below window openings, and that is to make it, if possible, regular; when this cannot be done the difference should be thrown in the centre of the opening, above the arch and below the sill. The alternate "perpends" or vertical joints should be invariably kept in line in the face work. The skewback of an arch is generally taken at a joint, though this is not necessary, as the bricks have to be cut to form the abutment or skew. It is better, however, so to arrange the springing, and the same coincidence of the top side of a straight arch with a brick joint is desirable.

#### EXTERNAL AND INTERNAL ARCHES.

In the openings of windows, owing to the reveal and recess for window frame, external and internal arches are necessary. In Fig. 2 we show half an elevation of each arch in a wall of 14in. thickness. The left-hand side represents the gauged face arch. The arch springs from a joint. On the right-hand side the arch is formed rough in two rings; here the bricks, being uncut, have parallel sides, and the lines representing the joints do not converge to a point, but are drawn as

tangents to a circle at the centre of arch, the diameter of which circle equals the thickness of a brick. The plans of alternate courses of the jambs and reveals are shown above.

#### EXAMPLE.

As an interesting example of ornamental brickwork, we give a sketch (3) of a portion of the upper part of the Rathhaus, Lubeck. Here we find moulded brick arches and recesses to the windows, the joints of which all radiate, the heads are filled in partly with horizontal courses of brickwork, and by a large circular opening, with cusps cut in shape very much like the cogs of a wheel, composed of radiating bricks. The semi-octagonal piers are also of brickwork, and are excellent examples of bonding, carried up and crowned by spirelets.

#### THE HYDROPATHIC ESTABLISHMENT AND ITS BATHS.—V.

By R. OWEN ALLSOP, Architect.

(Author of "The Turkish Bath: Its Design and Construction.")

A WELL-PLANNED building is the Tynedale Hydropathic establishment at Hexham, in Northumberland, the property of Mr. Frank G. Grant, and designed by Mr. W. Lister Newcombe, F.R.I.B.A., of Newcastle-upon-Tyne, who has kindly lent the tracings from which the accompanying illustrations have been prepared. The plans

GROUND FLOOR PLAN

TYNEDALE HYDROPATHIC ESTABLISHMENT, HEXHAM, NORTHUMBERLAND.

exhibit careful study in the placing of the bath-houses, and the accesses provided thereto. An arrangement—the desirability of which I urged in my first article—whereby separate means of approach for ladies and gentlemen may be gained, has here been made. As will be seen from the plans, the building consists of a main block having two side wings, the addition, on left, being an old house incorporated in the new building. Between the wings is placed a bath-house containing ordinary and hydropathic baths. Adjoining this is the Turkish bath, accessible from either set of baths at stated times, according as the bath is set apart for the use of ladies or gentlemen. Attached to the wings and in line with the baths, are projections containing staircases and lavatories, &c., those on the right being for ladies, and those on the left for gentlemen.

The usual accommodation is provided on the ground floor; but the culinary department, with many obvious advantages, is placed on the floor above. The bedrooms over the kitchen, &c., are for the domestics, and gained by means of the servants' staircase. The principal staircase is arranged opposite main entrance. A thoughtful provision is the separate arrival entrance—a consideration for the comfort of fresh arrivals at the establishment that all frequenters of hydropathics will appreciate to the full. A feature in this building is the arrangement of the combined bed and sitting room, a recess for bed, &c., being provided in these apart-

ments.\* A fine recreation-room is included, distinct from the drawing-room. The winter-garden, shown at the end of the corridor of left wing, is not, however, yet constructed.

The long bath-house is divided into two portions, giving accommodation for both ladies and gentlemen. On one side of either bath-room are dressing-boxes, and opposite are ordinary, shallow baths, with douches in adjoining compartments. Sitz and vapour baths are also provided. The Turkish bath consists of cooling-room, first and second hot rooms, and shampooing-room. It is handsomely fitted; the cooling-room is furnished with divans, and contains the plunge bath. Under the hot rooms, &c., are placed the heating apparatus for Turkish bath, and the boilers for steam supply, and for the hot-water system by which the corridors and public rooms are warmed.

The establishment is capable of accommodating 150 visitors, the main front block of building being four stories high. Its general arrangement is found most convenient, the carefully studied approaches to, and placing of, the baths, indicating a laudable effort to meet the peculiar exigencies of an institution of the nature of a hydropathic establishment.

The new schools, Millom, are warmed and ventilated by means of Shorland's patent Manchester grates, supplied by Mr. E. H. Shorland, of Manchester.

\* These rooms, Mr. Newcombe informs me, have been most successful, and are in constant demand.—R. O. A.

#### THE SYMBOLISM AND ICONOGRAPHY OF EARLY AND MEDIEVAL CHRISTIAN ART.—X.

By GEORGE ASHDOWN AUDSLEY, F.R.I.B.A.  
(Author of "Handbook of Christian Symbolism," and several works on Architecture and Art.)

#### THE COLOUR AND ARTISTIC TREATMENT OF THE NIMBUS.

UP to the present we have almost entirely confined our attention to the several forms the Nimbus has assumed in art; now, in concluding this branch of our subject, we may say a few words with reference to the colouring and the decorative treatments which have been followed by artists in its different renderings.

It will be remembered that in the course of our opening remarks on the Nimbus, we alluded to the very probable origin of this attribute in the sun—the source of life and light, and the object in nature which, above all others, uneducated humanity has in every age, and in almost all countries, looked upon with the greatest awe and reverence. Whether this supposition is correct or not, there can be no possible question that the Nimbus was first introduced in art—pagan art—with the view of conveying the idea of radiance or light encircling or emanating from the head of the person invested with it, and that when borrowed and modified by Christian artists it still retained much of its original signification is equally certain. Such being the case, one would suppose that

## FIRST FLOOR PLAN

TYNDALE HYDROPATHIC ESTABLISHMENT, HEXHAM, NORTHUMBERLAND.

artists would, with common consent, adopt the colouring and treatment best calculated to convey or express this idea of light and radiance. They have not, however, done so in a consistent manner, although such a treatment has in all periods been in use.

With reference to colour, yellow, white, and red would, of course, be accepted as covering, practically, everything in the nature of light, brilliant radiance, and fire; and so far as decorative art is concerned, gold, highly burnished, would take the place of all those colours. In Christian art, we observe such practices to have obtained, although not to the exclusion of other systems of colouring, as we shall presently show. No one at all familiar with the illuminated manuscripts of the Middle Ages can fail to remember the countless glittering gold Nimbi which adorn their miniatures, and which impart so brilliant an effect to the storied pages. In the manuscripts of the 14th and 15th centuries gold Nimbi, highly raised and burnished, were almost invariably used; and, accordingly, it is reasonable to surmise that in the higher class of mural paintings of those centuries gold was largely used for the Nimbi of sacred persons. In the illuminations of earlier epochs, we find gold Nimbi far more sparingly introduced; but when the metal is used in the ornamental portions of the manuscripts it is generally applied to the Nimbus. In early Byzantine manuscripts, large, plain, gold Nimbi are characteristic features; these are frequently edged with a narrow line of colour. In the West, the earliest examples of the Nimbus, met with in the Celtic and Anglo-Saxon manuscripts, are almost invariably in colours, frequently and appropriately in plain yellow. In the *Gospels of Mael Brith Mac Durnan*,

preserved in the Library of the Archbishop of Canterbury, at Lambeth, we find the curious portrait of St. John the Evangelist invested with a plain circular Nimbus of a bright yellow colour edged with white; whilst in the miniature of the Betrayal of Christ, of later date than the portrait just mentioned, Christ's head is invested with a plain red Nimbus; and the head of Judas has a white, St. Peter a green, and another apostle a red Nimbus. This manuscript was probably executed some time in the eighth century, but the miniature of the Betrayal is certainly about four centuries later. Turning now to the finest and most interesting Celtic manuscript in existence, the *Book of Kells*, preserved in the Library of Trinity College, Dublin, and attributed to the seventh century, we find some remarkable specimens of the Nimbus, both as regards colouring and surface enrichment. For instance, the Nimbus of the Virgin Mary has a bright pink field, powdered with small crosses and triplets of dots, in yellow and blue, and round the field is a border of tawny brown edged with white lines, and having a row of yellow dots in its centre. The artist here seems to convey the idea of a transparent field, for he has shown portions of the wings of two angels passing across the field and then behind the head. This effect is, so far as we are aware, unique, but it is not altogether happy. In the same manuscript, the Nimbus of the portrait of St. John, which accompanies his Gospel, is ornamented and coloured with all the minuteness and careful elaboration which characterise the early Celtic work; indeed, so elaborate is this Nimbus, that it is impossible to convey an idea of it in words.

In the "Royal Manuscript" preserved in the British Museum (marked 1 E 6), and

esteemed one of the finest monuments of Anglo-Saxon caligraphy and illumination in existence, we find the portrait of St. Mark delineated with a large, plain, circular Nimbus of a pale blue colour. In the celebrated Anglo-Saxon *Gospels of Lindisfarne* or *Durham Book*, the glory of the Cottonian Library, we find the portrait of St. Matthew invested with a very large, circular Nimbus, having a yellow field and a broad red border. These typical examples will suffice for our present purpose.

The stained glass of the Middle Ages furnishes the student of Christian Iconography with a fertile field for study. In the matter of the Nimbus, we find a series of treatments resembling very closely, in certain respects, those presented by illuminated manuscripts. Space will not permit us to treat the subject as presented by stained glass in anything approaching an exhaustive manner, and accordingly we may localise our remarks to the Nimbus as met with in the fine glass of the Cathedral of Bourges. In the large window in which are represented the scenes of the Creation specially relating to man, the Creator is invested with the tri-radiated Nimbus, having a white field and broad rays of red. In the scene, in the same window, in which God appears to Moses, in the burning bush, His head is invested with the same form of Nimbus, but with a yellow field and red rays. The two angels who appear along with the Deity have plain yellow Nimbi. In the scene of the creation of the angels, the Nimbus of the Almighty has red rays on a green field, whilst the angels have Nimbi of white, yellow, and red, all plain. In other windows we observe the Nimbus of our Lord with a light blue field and yellow rays; and the Nimbus of the Virgin with a red field surrounded by a narrow border of

white dots or pearls, whilst that of the infant Christ in her arms has a green field with yellow rays. The numerous other figures of apostles and saints depicted in the glass of this Cathedral are invested, for the most part, with unornamented Nimbi of blue and red. In the case of the figures of St. Peter and St. Paul a different treatment obtains: the Nimbus of the former has a light blue field, with a narrow white edging, and the Nimbus of the latter has a low-toned green field, with a narrow red edging.

From the examples above given, from both illuminated manuscripts and stained glass, it seems difficult to trace the adoption of any recognised system of colouring on the part of Western artists; on the contrary, one gathers the conviction that the colouring of the Nimbus was commonly held secondary in importance to the general tonal scheme of the subject. Contrast of colour was invariably secured; for instance, a red Nimbus was introduced when the ground colour of a window was blue, and a blue or green Nimbus when the ground was red. In other cases, when several heads appeared in one composition, the artist varied the colours of their Nimbi, probably to prevent confusion where the Nimbi overlapped, or to impart richness to the general effect when there was no overlapping or risk of confusion. We cannot help thinking that a Nimbus of white and yellow would in all cases have been equally effective, and certainly more correct from a symbolical point of view than either a dark blue or green one. For pictorial work, either in the pages of a book or on walls, panels, &c., the gold Nimbus, plain or rayed with ornament or appropriate colour, is unquestionably the most suitable and effective.

The Byzantine artists have from the earliest period of Christian art recognised the value and appropriate character of the gold Nimbus, and, accordingly, we find it almost to the exclusion of every other treatment in their ancient and late paintings. When their icons or figures are painted on gold grounds, and where there is every temptation to indulge in the display of rich colours, they have contented themselves by simply dividing the Nimbus from the plain gold ground by either raising its outlines and surface enrichments slightly, or defining its form by a system of sunk lines or dot work, executed, most probably, by a blunt tool whilst the *gesso* was in a wet state. In the *Guide to Painting* only one direction appears to be given for the rendering of the Nimbus. It is as follows:—

"How to make the Nimbus in Paintings.—When drawing an image, describe round the head a circle with a compass. Take a thread and dip it in thin gypsum in such a way that it will be well coated; then place it all round the Nimbus, following the line traced by the compass. You then move the compass round the inside of the circle described by this thread in order to make it regular. Use a fine thread for the Nimbi of small images, and a thicker one for those of large images. When the thread becomes fixed and dry add within it a coating of plaster if you wish the Nimbus to be in relief; then draw on it the ornament you wish to produce, and add some plaster on the foliage and on the threads in order that any desired prominence may be obtained. Lastly, scrape carefully the entire design, and gild it, finishing all off with a pointed bone. You will have to be particular in raising the ornaments to use different plaster to that which you employed at first; for this add a little ochre to give it a yellow colour."

These directions, although brief, are perfectly clear to anyone conversant with the decorative processes of the Mediæval artists. It is plain to see with what facility a Nimbus could be outlined and filled with elaborate and delicate designs by means of threads, of different sizes, dipped in a cream-like mix-

ture of fine lime and water; and also how easily many artistic patterns could be produced by filling in certain portions, between the threads, with plaster, left plain or manipulated by simple stamping or incising tools. Processes somewhat similar to that given in the *Guide to Painting* were commonly used by Western artists in their fresco and panel paintings, and always with satisfactory results.

There can be no doubt that the practice of richly ornamenting the field and border of the Nimbus originated with the Byzantine artists, and was conveyed by them into Italy. We observe their influence in this respect in the paintings of Cimabue, Duccio, Giotto, Orcagna, Simone Memmi, and Fra Angelico. Italian art, however, does not show any leaning to the extravagant treatment which is frequently found in the paintings of the Russian branch of the Greek Church; notably in those highly-prized representations of the Virgin and Child, which, beyond the faces, hands, and feet, are entirely covered with beaten plates of gold, studded with precious stones and pearls. Amongst such elaborate works are the "miraculous paintings" of the Virgin and Child of Vladimir (Russia) and Czenstochowa (Poland). We can quite easily understand the desire to impart the highest degree of richness, and to spare no expense in the embellishment of such ecclesiastical treasures as miracle-working pictures or images; and the application of elaborately-wrought discs of gold set with jewels, as Nimbi, to the heads of the sacred personages represented would naturally suggest itself. It is probable that this practice obtained to some extent in Western art; and that the valuable nature of the materials used led to the destruction of paintings so adorned; but no proof of this exists in connection with paintings. In goldsmiths' work the Nimbus, like the figure it invested, was very often of the precious metals ornamented with *repoussé*, enamelled, or set with precious stones. There is reason to believe that in some of the most costly and beautiful pieces of embroidery executed during the 13th and two following centuries, solid plates of gold or silver, gilded, were applied as Nimbi to the figures. These were probably enamelled in colours or studded with gems, so as to accord with the general effect of the silk and gold embroidery.

The Byzantine method of producing the Nimbus in relief was followed more or less closely by Middle-Age artists both in France and England, sometimes in the production of wall or panel paintings, and sometimes upon grounds of coloured glass. An examination of the 13th-century retable preserved in Westminster Abbey, and the series of figure subjects executed upon blue glass in the quatrefoils of the wall arcade in the Sainte-Chapelle, at Paris, will clearly show how such relief-work was executed by the workmen of the Middle Ages. The work in the Sainte-Chapelle is a restoration carried out in accordance with the original remains.

We may now return to the consideration of the colouring most appropriate for the Nimbus of sacred personages. It seems quite evident, mediæval precedent notwithstanding, that the correct colouring is that which best conveys the idea of radiance or light, and it is desirable that any appearance of opacity and weight should be avoided. In stained glass the desirable brilliancy and transparency can be easily obtained by the use of white and yellow only or with the sparing introduction of flame-like ruby and sky-blue. Beyond these we do not advise the artist to venture. At this point we may give some remarks by Didron on the subject. After drawing attention to the fact just commented on, that gold or yellow and white are the most appropriate as representative of light, he says:—"The colour of the Nimbus is occasionally symbolical—as is proved by the

black Nimbus—'nimbe en deuil'—given to the traitor Judas: still, in numerous instances, it is purely hierarchical. The form, therefore, of the Nimbus having been ingeniously rendered the vehicle of a strongly-marked hierarchical distinction, it seems appropriate that the intention of the form should be heightened and still further carried out by the colouring. To cite an example in illustration. The Public Library of Strasbourg contains a magnificent manuscript (*Hortus Deliciarum*), which, if tradition may be credited, was written and painted by Herrade, Abbess of the Convent of Sainte-Odile, in Alsace. It is an encyclopædia of all the sciences known and practised in the Middle Ages; and appears to be the precursor of the admirable work of Vincent de Beauvais, entitled *Speculum Universale*. Towards the conclusion of the manuscript is a painting of the celestial courts. Christ is delineated in the highest place, invested with a Nimbus and crown of gold; then come the nine orders of saints intermingled with angels, and disposed in the following order:—Virgins, apostles, martyrs, confessors, prophets, patriarchs, the chaste, the married, and the penitent. The four first orders, the most exalted of all, have the Nimbus of gold. Prophets and patriarchs, the saints of the Old Testament, and who knew the truth imperfectly only through the veil of metaphor and allegory, have a Nimbus of silver. The Nimbus of the chaste is red; that of the married green, and that of the penitents yellowish, and slightly tinted. Colour is evidently employed in these instances as a hierarchical distinction; it loses its brilliancy in proportion as it descends from a lofty to an inferior grade, after which point the title of saint is no longer awarded, and the persons represented are regarded only as ordinary mortals. It may be observed, in conclusion, that the hierarchy of colours might easily, in the ideas of the Middle Ages, have allied itself with symbolism. Gold is the most radiant of all colours, and it is here awarded to saints of the highest eminence.\* Silver, the colour of the moon, which, though inferior to the sun, is ever his constant attendant, stands next in rank; then red, or the colour of fire, the attribute of those who struggle against passion, which is inferior to the two metals, gold and silver, to the sun and moon, being merely an emanation from the former; then green, the colour of hope, appropriately assigned to married persons; lastly, a sort of yellow, an equivocal tint, partly white and partly yellow, a mixed colour given to the saints who had formerly been sinners, but, by prayer and penitence, had again become acceptable in the sight of God." In the above quotation allusion is made to the black Nimbus sometimes given to Judas, and we may mention one example. There is, or was some few years ago, a fresco painting of the Last Supper in the apse of one of the small churches in Athens, and in this painting all the apostles are invested with the Nimbus. The Nimbi of the good apostles are of bright colours, such as golden yellow, white, and light green; but the traitor Judas has a black Nimbus. Judas is an apostle, and is accordingly entitled to the attribute; but the artist has most distinctly marked his fallen state. The radiance has ceased to surround his head because his soul is darkened.

We have directed attention to the desirability of giving the Nimbus the effect of brightness and transparency and of avoiding any decided appearance of opacity and solidity, and it is just worth while noting the few words Didron says on this subject:—

\* The position of the Virgins in this highest rank is not in accordance with the canon of iconographic art. Probably, as the painter was a nun, she paid this special honour to her sex and vows. Such an irregularity as this is not uncommon.

"The Nimbus, up to the twelfth century, was in the form of a disc, but fine and attenuate. A very beautiful Greek manuscript\*, of the 10th century, preserved in the Bibliothèque Royale, at Paris, contains a personification of Night, under the form of a woman clad in black robes. Her head is encircled by a luminous and transparent Nimbus, through which, as through the glass of a telescope, the stars of heaven are discernible. Even if the Nimbus is not, in all cases, equally diaphanous, it is always so lightly traced as to suggest the idea of transparency, and of the artist's desire to figure it as a luminous atmosphere." The Nimbus of the Virgin in the miniature in the *Book of Kells*, already described, seems to clearly support Didron's supposition. Didron continues:—"During the 12th, 13th, and 14th centuries the Nimbus became more dense, narrower, and extending less beyond the head; it had till then been transparent, but now became opaque. It was nothing more thenceforth than a rude disc, a kind of plate, a sort of circular pillow painted or sculptured behind the head. It no longer, as in the preceding periods, permitted the sky and the surrounding landscape to be seen through it. It was an opaque wall, not transparent glass. Such is the Nimbus given to God, the saints, and angels, in the Cathedrals of Paris and Chartres."

Turning to mosaics, we find the Nimbus almost invariably with a field of gold, simply outlined by a rim of colour or by a narrow border. Throughout the numerous figure subjects which adorn the walls of the Cathedral of Monreale, near Palermo, the Nimbi of God and all the angels and saints are of gold, outlined by narrow rings of red, blue, or white. With the single exception of the Nimbus given to our Lord, every one has a plain gold field. The Nimbus of the

Creator, in the scenes of the Creation, is entirely unadorned; whilst that given to Christ, in the New Testament series, is invariably tri-radiated: the rays being also of gold, like the field, simply defined by thin lines of blue or red. In only a few cases are the rays patterned in any manner.

We may now close our remarks on the Nimbus, and enter upon the consideration of its extension, the Aureole.

(To be continued.)

#### HOUSE AT LLANDAFF.

THIS house has just been completed for Mr. G. E. Halliday, member of the firm of Halliday and Anderson, architects, of Cardiff, by whom the designs were prepared. Mr. John Haines, of Cardiff, was the contractor. The lower part of the house is built of Blackwood stone, with Bath stone dressings. The upper part and roof are covered with Broseley tiles.

#### MR. WATERHOUSE ON THE SHEFFIELD MUNICIPAL BUILDINGS COMPETITION.

THE annual distribution of prizes and medals place on Monday evening, when the President of the Institute, Mr. Alfred Waterhouse, R.A., delivered an address to the students and members. There was but a meagre attendance. We published the prize list, with some remarks on the designs submitted, in our last issue, p. 88. Mr. Waterhouse, having alluded to the recent untimely decease of Giuseppe Brentano, who gained the first prize in the Milan Cathedral competition, in which the President was an assessor, continued: I should be glad to think the day not far distant when competitions would be rarely, if ever, resorted to, except for works of the greatest national importance. I lament their frequency chiefly because of the enormous amount of unproductive labour they involve; but I do not see at present any tendency towards their diminu-

tion. This being so, it seems most important that those who are concerned as assessors in drawing up instructions should see that they are prepared not only to secure the best results from the promoter's point of view, but also to subserve as much as possible the interests of the profession—first, by saving the architects competing from all unnecessary work; and secondly, by not hampering competitors with vexatious restrictions, thus leaving them free to solve in their own way the problem put before them, without the feeling that if all the accommodation asked for is not exactly of a certain size, and every room of certain dimensions, they will be adjudged out of the competition. I would have every competitor put as nearly as may be in the position of an architect acting for a private client, who, though he may have suggested his requirements, would probably listen to his professional adviser if he gave good reasons for not literally adhering to them in all cases. I have endeavoured, when acting as assessor, to use my influence to keep the instructions thus elastic; but I have frequently had to regret that they had not been more so, when, after the designs themselves had come under review, some of general excellence had to be set aside for breach of conditions in some point of minor importance, on which the instructions unfortunately had been allowed to speak too decidedly. Having lately been engaged upon such a labour in the first or sketch competition for the Sheffield Municipal Buildings, I have thought that I could not do better than bring before you some special facts in connection with that competition, and some special considerations which may prove of use to some of my hearers. The instructions in this case were issued in August last, and invited certain drawings to  $\frac{1}{4}$  in. scale—viz., a plan of each floor of the proposed building, two cross sections, and one elevation. They were all to be on stretchers of the smallest possible size—2ft. by 1ft. 6in.—so as to be kept near the eye-line when hung on wall or screen, and easily handled for reference. No mottoes or distinguishing borders or devices were allowed. When a case containing a design was opened, it was numbered by a progressive number, and every drawing and docu-

\* Psalterium, Greek MS. No. 139.

ment within the case was marked for identification with the same number. Alternative schemes were ruled out of court altogether; for, as a rule, those architects whose exuberant imagination would induce them to send in alternative schemes, or to cover their plans with flaps showing how they could vary their arrangements, lose much by so doing. They may show themselves men of varied resources, but hardly architects convinced of the perfection of the scheme they propose for adoption; and the time expended in preparing two schemes would be much more profitably spent in perfecting one. I must, however, leave Sheffield for the moment, to tell you of one exception to this rule which I encountered many years ago. It was in a competition for the Bristol Assize Courts. I was asked by the Corporation to assist them in awarding the three prizes they had to dispense for the first, second, and third best designs among those sent in which agreed with their instructions. I had not much difficulty in discovering what, in my opinion, were the best of the series, nor of placing them in their order of merit; but, though they were in different types of Gothic—one round-arched, another 13th century, and the third of a later style—I was somewhat troubled in divining, and that for two reasons, that they were all by the same hand. At first it was difficult to be sure about it, as the lettering, mounting, and colouring of each set were entirely different, as well as the styles and disposition of plan; but they had all a vigorous character and individuality about them which appeared to flow from one and the same source of inspiration. Secondly, they all showed on their block plan an insignificant feature of an adjacent building, which I had myself observed in visiting the site, but which was not on the lithographed block plan given to each competitor, and which was omitted from all other designs in the room. When meeting the committee, therefore, for the purpose of making my report, I thought it desirable to inquire whether it would, in their opinion, be proper to give all three prizes to one competitor, provided the three designs best, according to the judgment of the assessor, should prove to be by one and the same hand. At first they said "No"; but one of the committee, who appeared to be conversant with affairs of the turf, remarked that if he entered three horses for a race, and they all three reached the winning-post before the rest of the field, there was no reason against his being accredited with the first three places; and that what was fair with horses was equally fair with architects' designs. This argument settled the point. I gave my award, the seals were broken, and the late gifted E. W. Godwin carried off all three premiums. What Edward Godwin might venture upon with success, it is not given to everybody to imitate with equal success—and as it was, this brilliant exploit did not secure him the execution of the work. Another competition was decided upon, in which, after what I have told you, I declined to act again as assessor. But to return to Sheffield. The accommodation there required was given in the form of a schedule, in which the sizes of rooms were only suggested sizes. A general compliance with the dimensions contained in this schedule was all that was insisted upon. The total number of superficial feet of suggested accommodation was also given at the end of the schedule, the blank columns of which had to be filled in by each competitor, to show at a glance what he was providing in each particular case, and also what was the total aggregate of his accommodation. This schedule so filled up has been of the greatest use in the examination and comparison of the different designs. No sooner were competitors fairly at work than numberless letters came from them on the subject of the instructions. They did not like being compelled to limit the amount of their work, and would have preferred sending in more drawings. Partners would have liked each to send in a separate design. Others wanted to make more elevations, and detailed drawings and perspective views. On the 9th October a copy of the printed replies to 121 questions was sent by the town clerk to everybody who had obtained instructions; after this we answered no further questions. Early in December the designs were sent in—178 in all. One of the competitors transgressed the instructions by applying a motto to his stretchers. Three or four other designs were sent in so unfinished as to be hardly in a condition to enter the lists; while a few—but very few—had not kept to the letter of the instructions in other points. On the whole, however, the

competition was a great success. An unusually large number of good, thoughtful designs were submitted, many of them in their elevation showing an excellent originality. Whether the shape of the site, verging towards a triangle, suggested it or not I cannot tell, but a considerable proportion of the plans bore too great a resemblance to a recent building erected for a nearly similar use, the details of which I have reason to be familiar with, and which in some cases has been followed even to its faults. One of the greatest faults in the Manchester Town Hall has always seemed to me the position of its council-chamber, overlooking as it does Albert-square, a position its architect thought unavoidable owing to the public hall occupying the centre of the site. But in Sheffield no public hall is required, and, therefore, that position is available for the council-chamber; as is also the south front, where there is a good light, and no thoroughfare for carriages. Perhaps owing to competitors not having been allowed to submit an elevation of the south front, which will in reality be very conspicuous even from a distance over the adjoining disused churchyard, many designs have a very jagged outline on plan on this side, and which their authors would find it very difficult to clothe with dignity, or even picturesqueness, were they asked for its elevation. The west front, an elevation of which was alone asked for in this competition, is about 200ft. in length. Across the adjacent street on the north is a new building (the Yorkshire Penny Bank and Albany Hotel) about 56ft. high, while on the south is the before-mentioned churchyard, with the church in its centre having a tower surmounted by a cupola. The height of the adjacent buildings does not appear to have been duly considered by every competitor; perhaps some had not visited the site; and no doubt the instructions suggesting the required accommodation almost exclusively on the ground or first floor had a good deal to do with the unfortunate fact that this, the principal front of the Municipal Buildings, was sometimes drawn with a parapet not more than 45ft. from the street level. The want of height in the horizontal features of the front has been, however, generally made up for either by a central tower on a line with the front, or by one set back behind the state apartments, which apartments naturally, in the greater portion of the designs, occupy this front (in the latter position the effect of such a tower would be in great measure lost), or by a tower at one or other extremity of the front. In some cases this lateral tower was placed, not on the western front at all, but facing the side street, just behind the principal apartments, where it would fulfil the useful function of interposing a break between the lofty state-rooms and the lower business offices which overlook the side street. These towers—many of them—show great ingenuity in their design. One had its square trunk surmounted by four gables, not subtending the whole width of each side, but long and slender, with a pierced arcaded parapet on either side in the style of Bishop Gower of St. David's, through which passed the high-pitched, slated, and hipped roof, filling in the angle spaces between the gables. The whole was surmounted by a well-designed *flèche*, and formed altogether a very original and elegant campanile. I dwelt on some of these Sheffield towers with tenderness, and, when they had to be put aside, with sincere regret. Many of them were of great beauty, and some few were entirely free from all suspicion of ever having served an ecclesiastical turn in another state of existence—in fact, they seemed quite original. In some few instances a dome took the place of a tower. When placed behind intervening roofs the dome suffers more than the tower; but in one or two cases the dome was brought to the front of the building. These massive features do not in all cases stand on sufficiently massive supports. We are most of us occasionally tempted or forced to use iron or steel more freely than is desirable in support of walls; but would it not be well to make a rule to dispense with any feature of a non-essential character in a monumental stone building whenever its introduction demands the use of iron girders and stanchions? Another frequent feature at Sheffield—like the tower, entirely optional, neither being mentioned in the instructions—was the *porte-cochère*. Among the 121 questions was one asking whether such a feature might be thrown out beyond the prescribed area

of the site. Leave to introduce this feature being in this way obtained, by far the greater part of the competitors availed themselves of it, but not generally to the improvement of their elevations. Why is it so difficult to make the *porte-cochère* marry with the elevation against which it is placed—unless, indeed, the same treatment (*e.g.*, arcading) is carried through the whole of the ground-floor of the front, and the *porte-cochère* also? By the great projection of the *porte-cochère* it hides half the front from view if seen in quick perspective; by its height and projection it seriously dwarfs the elevation; or, if to avoid these disadvantages it is kept very low, it looks very mean. Lastly, its peculiarities of construction involve too often a want of harmony between it and the building it serves. The best treatment I have seen is when the carriage-way goes behind an open arcade which supports an advancing central gable; and where the wings of the façade also advance there is much to be said for this arrangement. This, however, was not in favour in Sheffield, though in one case the carriage-way was carried within the walls of the building. The main entrance seemed to be in many cases intended to provide a pair of heavy outer doors only, without the usual inner swing-doors, two pairs of which, one within the other, are necessary to keep out the wind on a western front. At Sheffield I again observed what is but too general in most competitions, that the anxiety to get all the accommodation of the suggested dimensions into his plan has often prevented the competitor from observing that his rooms have been made of a proportion which would be intolerable if carried out—*e.g.*, 50 × 30 × 12.6 high. Also, many plans that looked at first most promising were found to have their walls over voids, the chimney-stacks on the lower story giving no account of themselves on the upper floors, and staircases shown on plan which could never have been constructed. Then, again, there is the great light question. In the majority of cases the use to which the light from small areas was put was the best possible—that is, it was used to give side light to corridors, which, as they were seldom more than 7 or 8ft. wide, could of course be lighted across their width much more easily than a room 30ft. from back to front could be. And yet in other designs there were such rooms only about 12.6 high, and with windows inconveniently low for a room of such a depth, which windows were expected to give light enough for important office-work in a smoky town, where the buildings opposite were lofty. When such windows look into a deep and narrow area, nothing but disappointment must be the result. The exceptional favour some competitors expect from the sun fills me with amazement. For the sake of light, air, general cheerfulness, and architectural effect, it is most desirable that internal areas in a building should be as few and as large as possible, instead of many and small. If one large area be adopted instead of many small ones, which has, of course, the advantage of securing a much better architectural effect, it may be difficult to light the corridors only from this source; but if thus deprived of a continuous side light by the interposition of rooms looking into the area the skilful designer will see that they are never dark, especially at their extremities, where they turn, or where there is a change of level—if, indeed, such be necessary in any case. With regard to staircases, it ought not to be necessary to say that a principal flight of stairs in such a building could hardly with propriety have steps less than 6ft. or 8ft. wide, with treads and risers 12in. by 6in., or, better, 12½in. or 13in. by 5½in.; and that until you are able to secure so much ease of going and space in a single staircase it would be folly to think of double flights in the same staircase, still less of twin stairs in all respects repeating each other. One dignified stairway, well considered, thoughtfully designed, with something unusual in it, if attainable without sacrifice of convenience in any way, is infinitely to be preferred to a couple of commonplace, steep, and cramped ascents. In one design additional charm had been secured to such a single principal stairway by allowing a business staircase to be separated from it merely by a stone screen or open arcade, so that one stair could be seen from the other, greatly adding to the effect of both. These business stairs also should be so placed as to be as accessible as possible from the offices in their neighbourhood, thus avoiding all needless traversing of corridors to reach them; and yet none should be

inserted not absolutely needed. In no case should a staircase run up in the ordinary width of a corridor, so reducing its width and the view down it, as is common in gaols, and there permissible for a strictly utilitarian reason. In municipal buildings in places where, as in Sheffield, there is no special residence for the chief magistrate, there will almost certainly be a suite of reception-rooms. These rooms and the approaches thereto should be so arranged as to be cut off from the business portion of the building when required without in any way interfering with access to the latter; further, such rooms as the council-chamber and the committee-rooms, while having approaches from the corridors of the reception suite, should invariably be accessible also from the departmental corridors for ordinary business purposes. The corridors of approach to these reception-rooms should be at no point cramped, especially at the head of the grand staircase, or, on crowded assemblies, an inconvenient block will necessarily ensue. Sanitary considerations make it imperative that closets should each be lighted with a separate window, and that the ante-room of approach should be lighted and ventilated otherwise than through the closets themselves. This is not always remembered by architects competing. One well-lighted and well-ventilated closet is worth half-a-dozen of the sort one so frequently sees on competition plans. It is also most desirable that such sanitary appliances should be kept as much as possible together both on plan and vertically. These are some of the points I thought most open to criticism in the Sheffield sketches, but there is no doubt that the design of the elevations especially is of a higher average than that which has distinguished some late competitions, as those of you will see who care to visit Sheffield, where all the designs are now on exhibition, except the six selected for the final competition, and those whose authors wished to withdraw them before the exhibition. Wherever the authors are so willing, their name is attached to their designs, and I trust that the publicity thus given to merit may be some compensation for the absence of other remuneration. In the case of the six, their sketches are to be hung side by side with their elaborated designs when complete; but in accordance with precedent, for which there is something to be said, they are not to be exhibited until the final competition is over. In many a competition the expenses to which our profession is put before any contract drawings are prepared for a building thus competed for would, if accurately calculated, be found to amount to many times the total of the successful candidate's commission. So that, except for the educational benefit to be derived from having designed and elaborated the details of some important building, there is to the body of the candidates very little profit to be gained from a system which most of us deplore, but do not at present see how to supersede.

A vote of thanks was heartily accorded the President, on the motion of Mr. J. MACVICAR ANDERSON, seconded by Mr. J. DOUGLAS, of Chester.

#### BOOKS RECEIVED.

*Mensuration made Easy, or the Decimal System* (Effingham, Wilson, and Co.), is the nineteenth edition of this useful little manual intended for the artisan and mechanic, though of much value to all persons. The applications of the decimal system to everyday requirements, to common fractions, to the solution of problems in mensuration, and mechanics, are explained, giving after each rule a worked-out example.—*The Insurance Year Book for 1890* (London: Simpkin, Marshall, Hamilton, Kent and Co.) is the fifth annual issue of this useful publication. The new features include two elaborate tables showing the reversionary and cash bonuses granted by various life offices, and sections dealing with mortgage and capital sum insurances.—*The Science of Building*, by E. WYNDHAM TARN, M.A., Architect; Third Edition revised and enlarged (London: Crosby Lockwood and Son), is one of the best expositions of the science of construction, or rather the mechanical principles involved in the architect's work, we know of, and is therefore well adapted for the student of architecture who wishes to master the theories of retaining walls, arches, and cupolas, timber and iron construction, hydraulics, and other subjects. As an elementary textbook, Mr. Tarn's treatise

ought to be placed in the hands of every pupil, as the mathematics supposed to be known are easily acquired. Mr. Tarn does not forget to acquaint the student with the principle of graphic statics or Maxwell's principle of stress diagrams, effect of corbelling out, the mode of estimating the stability of hammer-beam roofs, arched roofs. Shoring is also treated, and the manner of calculating the strength of shores and struts. The strength of stanchions and long columns, wrought-iron beams, and rolled joists, the effect of heat upon iron, are discussed, and the chapters on fluids, flow of water in pipes, strength of water pipes, the pressure of wind on buildings, ventilation, and lightning conductors are valuable additions to a work of this kind. The author has explained the principles of mechanics which are necessary to be known without undue prolixity. One of the additions to the present edition is the rules for finding the strength of iron stanchions and struts of different sections, angle, trough, cruciform, and H shapes. Professor Rankine's formula is given for this purpose. For a long pillar the formula is:

$$W = \frac{f \times A}{1 + a \left( \frac{l}{d} \right)^2}$$

where A is the sectional area of pillar, l the length, d the least diameter, all in inches; f and a quantities found by experiment for different materials, and W the breaking weight in tons. The value of f for cast-iron pillars is 35.7 tons, that of a =  $\frac{1}{400}$ , or .0025. For wrought iron, f = 16

and a =  $\frac{1}{3000}$ , or .00033. The greatest deflection

in a long pillar or stanchion consistent with safety is proportional directly to the square of the length, and inversely to the thickness. The friction of water in pipes, and tables of the strength of timber, stone, and steel, are also given in the revised edition. Perhaps a few more numerical examples would add to the value of the book amongst students and others. There is a commendable brevity in the treatment of the subjects.—*Ipswich Past and Present*, by W. VICK, Part XII., now before us, completes the first volume of these platinotype views in and about Ipswich. The subjects are the Ancient House, a Merchant's House in Fore-street, and a portion of the Ramparts, which, with the cottages behind, has now been removed to make way for a stay factory. Part XIII., beginning a second volume, contains views of St. Nicholas Church in 1865, showing the building's appearance prior to its restoration from Mr. E. F. Bisshopp's plans a few years since; the King's Head in King-street, removed to make way for Mr. Brightwen Binyon's Corn Exchange; and three 15th-century carved angle posts still remaining in Silent-street, Carr-street, and Foundation-street; the subject of the last-named being the fable of the cowed fox preaching to the geese. The photographs in Part XIV., include St. Margaret's Church in 1865, since restored from Mr. Frederick Barnes's plans; the plaster fronted Lion and Lamb Inn in Angel-lane, St. Clement's, with oriel, rich barge boards, and tiled roof, often the subject of sketches, and a view of the Orwell and Hog Highland from the Promenade.—*Alternative Elementary Physics*, by JOHN MILLS, of the Normal School of Science, illustrated (London: Chapman and Hall), is a useful little volume to meet the requirements of the Department of Science and Art for the "alternative course." The subject is treated to give the student a clear conception of the laws of sound, light, heat, magnetism, and electricity. Each of these is explained by an experiment of the simplest kind, and illustrated. For the object proposed, as well as for all students of elementary physics, the book of Mr. Mills will be found of service.—*Perspective Charts for Use in Class Teaching*, by HENRY A. JAMES, M.A. (London: Chapman and Hall), is a valuable aid to teaching perspective, which we cordially recommend both to instructors and pupils. The object of the author is to give an outline of a course of study introductory to perspective drawing which can be used as a table of reference. The beginner has generally a very vague notion of lines and planes. This chart facilitates the acquisition of this necessary knowledge. Thus the classes of lines, those perpendicular and inclined to the picture plane, are illustrated by diagrams on which their relative positions to the picture plane are shown. The

projections of lines on the plane are shown by other diagrams illustrating the perspective delineations of parallelepipeds, prisms, and other solids. Chart C illustrates the principle of finding "starting" and "vanishing points." The projection of points is similarly shown by reference to the two planes, the horizontal and the picture plane. If the student knows the starting point and vanishing point, the direction of a perspective line is assured. Constructions necessary for finding points of lines not otherwise determinable, such as horizontal, vertical, and slant lines, are lastly considered. Mr. James's charts illustrate by a few diagrams the fundamental laws of perspective, and ought to be in the hands of every student.—*Solutions to Questions of the May Examinations of the Science and Art Department, 1881 to 1886, Pure Mathematics, Stages I. and II.*, by THOMAS T. RANKIN, C.E. (London: Chapman and Hall), contains the working out of questions in arithmetic, geometry, algebra, and trigonometry. For students preparing for those and similar examinations, the solutions will be found a valuable aid.—*Handbook of Quantitative Analysis*, by JOHN MILLS and BARKER SMITH, of the Normal School of Science (London: Chapman and Hall), includes examples in quantitative operations, analysis of alloys, minerals, and ores, commercial products, water, gas, and organic analysis, &c. The requirements of students for the honours examinations on inorganic and organic chemistry have been mainly consulted. The book is well printed and illustrated.

#### BRICKMAKERS IN COUNCIL.

A WELL-ATTENDED meeting of brickmasters was held at Cannon-street Hotel on the 13th inst., at which the leading manufacturers of the various districts supplying the London market were present. The following resolutions were proposed, seconded, and unanimously passed:—

- (1) "That in the opinion of this meeting of brickmasters supplying the London market, an advance in the selling price of bricks is imperative to meet the increased cost of fuel and materials, and the advance given in the price of labour."
- (2) "That in the opinion of this meeting it would prove of great advantage to the industry if brickmasters supplying the London district would co-operate in dealing with the various labour questions as they arise."

#### CHIPS.

Daybrook Church, near Nottingham, has just been reopened. Among the fittings in the interior may be mentioned a handsome oak pulpit, prayer desk, and a lectern, all of which were intrusted to Messrs. Jones and Willis, of Birmingham and London, for execution.

A new Congregational church in Hawkshead-street, Southport, will be opened next week. The style is 13th century English, the only other example in the district being a newly-erected Wesleyan church in Southbank-road, Southport. Red brick has been used, with Longridge stone dressings, and the angle is marked by an octagonal tower surmounted by a stone spire. The interior consists of a broad nave, the side aisles being used as passages only. The seating is of pitchpine, and the accommodation for 450 persons. Messrs. W. Waddington and Son were the architects, and the cost, exclusive of boundary walls, has been £3,000.

The memorial stone of the Free Church at Airdrie, now being renovated at a cost of £3,000, was laid on Friday. Mr. A. McGregor Mitchell is the architect.

An infants' department just added to board schools in Sharrow-lane, Sheffield, was opened by Mr. Mundella, M.P., on Friday. It consists of an assembly room and three classrooms, separated by movable divisions, and provides accommodation for 330 infants. The amount of the contract is £1,800, including the cost of covered way and caretaker's house. The architect is Mr. C. J. Innocent, George-street, Sheffield, who designed the original schools, built two years since; and the contractors are Messrs. Ash, Son, and Biggin. Mr. J. Laidler has acted as clerk of the works.

During the past year Mr. Charles Bill has made considerable additions and improvements to Farley Hall, Cheadle, from designs by Messrs. Naylor and Sale, architects, Derby, including an enlargement of the drawing-room, several additional bedrooms, and the lighting of the hall and premises with the electric light. To celebrate the completion of the works, he gave a supper to the workmen at Farley on Saturday evening, when about 45 of them sat down to a substantial repast. Mr. Bill proposed the health of the men, coupling with it the name of Mr. John Fielding, builder, of Alton, the contractor.

ISAIAH: A DESIGN OF PANEL FOR CHURCH DECORATION.—  
MANCHESTER PALACE OF VARIETIES.—RALEIGH TEMPER-  
ANCE HOTEL, DARTMOUTH.—DESIGNS FOR CEMETERY,  
CHAPELS, AND LODGES.—THE SCREEN, ABBEY DORE  
CHURCH.—HOUSE AT LLANDAFF.—TWO PIECES OF  
FURNITURE AT THE NEW GALLERY.

## OUR LITHOGRAPHIC ILLUSTRATIONS.

## DESIGN FOR CHURCH DECORATION, "ISAIAH."

This is a reproduction of a design in chalk by Mr. T. W. Bladen for a painted panel. It was exhibited at the "Arts and Crafts," and was awarded there, by the Society of Arts, a bronze medal and a £5 prize. "Isaiah" is represented as though speaking to the people one of the most characteristic texts from his Prophecies, "Comfort ye," &c., which is inscribed on a label behind. The background is divided up into smaller panels of conventional ornament.

## MANCHESTER PALACE OF VARIETIES.

This building (a double-page illustration of which we give) is now in course of erection at the corner of Oxford-street and Whitworth-street, Manchester. The theatre will have a frontage of 103ft. 6in. to Oxford-street and 139ft. 6in. to Whitworth-street. The auditorium will be 90ft. by 66ft., and the height from the pit floor to the spring of the dome will be 60ft. A novel feature in the planning of the auditorium is that it is placed parallel with the stage, and not in prolongation of it. The block of buildings will stand isolated from the surrounding property. The staircases, corridors, and all portions of the house used by the public will be fireproof. The dressing-rooms and stage are so arranged that each portion can be detached in case of fire. An interesting feature connected with the building is that access can be had from the main tier to the winter garden and foyer on the first floor, the dimensions of which are 66ft. by 27ft., and an outside loggia, connected therewith, fronts Oxford-street. It has been so designed that the stage will be viewed from both the foyer and winter garden. The fireproof staircases, circle tiers, doors, partitions, and auditorium and stage ceilings will be executed by the Titancrete Co., with their patent fireproof materials. The decorations will be carried out by Messrs. Heighway and Depree, of London. The building is being erected by Messrs. W. Brown and Son, contractors, from the designs of Messrs. Alfred Darbyshire, F.R.I.B.A., and F. Bennett Smith, the architects.

## THE RALEIGH TEMPERANCE HOTEL AND NEW POST OFFICE, DARTMOUTH.

This building, which is the first erected on the new embankment, is now completed and open for business. It is within fifty yards of the railway station, and is erected at the corner of two streets, which gives it the advantage of two frontages, one of 37ft., the other of 91ft. Four lofty stories rise to the height of 52ft. above the ground-floor level; the line of frontage is broken with gables, chimneys, and oriel windows; the walls are built to the height of the first floor with red bricks, the doors and windows having moulded Bath stone dressings; the projecting chimneys are carried on moulded brick corbels,

the shafts and tops are built in cement, the remainder of the building is half-timbered, the timber used being of red deal of solid proportions, all moulded and framed together. The overhanging upper stories have balconies the width of the building; the high-pointed gables have deep ornamental barge and finials. The spaces between the timbers are filled in with green and red slates cut to fancy patterns; those parts under windows have carved panels. The accommodation provided in the hotel consists of hall, two dining-rooms, five sitting-rooms, manager's room, billiard-room, thirteen bedrooms, four lavatories, bath-room, housemaids' room, kitchens, and offices. The staircases are constructed with pitch pine 4ft. wide, square sunk moulded newels with turned heads and pendants, moulded strings and turned balusters, and moulded mahogany handrail. The windows of sitting-rooms open on balconies constructed with wood, having turned newels and balusters. The floors are laid with coloured tiles. The post office, which forms a part of the hotel, has two entrances, and consists of main office 59ft. by 22ft., postmaster's private office, foreign mail office, two lavatories, &c. The fittings are of pitch pine. The whole of the works have been carried out under the personal superintendence of the architect, Mr. E. H. Back, of Dartmouth, the builders being Messrs. Row and Watts, of Dartmouth.

## BUILDING NEWS DESIGNING CLUB.—A CEMETERY CHAPEL.

See description on page 151.

## CHANCEL SCREEN, ABBEY DORE, NEAR HEREFORD.

The Cistercian Church of Abbey Dore, as it now stands, is but a fragmentary relic of the vast abbey which once stood on the banks of the Dore, in the Golden Valley, on the foundation laid by Robert de Ewias, in the days of Henry I. Those who wish to see a complete measured monograph of this beautiful example of pure English architecture will find it in Vols. VI. and VII. (1872-74) of the "Architectural Association Sketchbook," and in the Sessional Papers of the R.I.B.A. a lecture on the church was printed in the volume for 1851 by J. Clayton, the author of "Ancient Timber Edifices in England," published in 1846. The building, as it exists, includes the choir, 28ft. 3in. wide with a processional path, 17ft. 4in. wide, round the east end, forming three chapels, and divided into compartments by detached columns of much beauty supporting the groining of the ambulatory. The transepts have eastern aisles for chapels, but the nave has gone. The columns can be traced in the churchyard, showing that the nave, as usual in Cistercian churches, extended about twice as far as the choir. The Chapter House, Refectory, and other conventual buildings at Abbey Dore were placed on the south side of the church. The restorations of the building by Lord Scudamore in 1642, or some years earlier, are of considerable interest to us now, and he added the celebrated screen, pulpit, and pews of excellent Renaissance character. Mr. Wyatt Papworth gives the date of the screen as 1634, and suggests that it was designed by John Abel, who did Leominster Town Hall, Warwickshire, as well as Hereford Town Hall and Market House, built in 1622. We publish an excellent photograph of this remarkable screen by Messrs. Poulton and Son, of Lee, Kent. It is 25ft. 9in. wide, and stands east of the great crossing under the central tower. The whole composition is very spirited and curious, though coarse in its details. The immense altar slab of marble standing on three clusters of massive circular columns, about 2ft. high, is the original altar, and was restored to its ancient use by Lord Scudamore.

The question whether the Amalgamated Society Carpenters and Joiners is a Friendly Society or a Trade Union was argued on Saturday in the Queen's Bench Division. Acting on the assumption that it is an unregistered Friendly Society, the Middlebrough justices had made an order against the secretary of the Society to pay a sum claimed by a member. Mr. Baron Pollock and Mr. Justice Wills reversed that decision, holding that the Society is a Trade Union, over which the magistrates have no jurisdiction.

A new brewery is in course of erection near the Cobden Bridge, Bitterne, from plans and under the superintendence of Mr. E. Cooper Poole, of Southampton. Mr. John Witt, of Bitterne, is the builder.

## TWO PIECES OF FURNITURE AT THE NEW GALLERY.

THE Writing Cabinet by Messrs. Morris and Co., from the designs of Mr. Jack, though beautifully made, and not without a certain "go" and novelty in its style, cannot be spoken of in unmeasured praise. We think there is something heavy and ungainly about the lower portion, which gives it the appearance rather of a stand for the upper cabinet than as forming a part of a consistently designed whole. This is, no doubt, due to a great extent to the abrupt line where the slope of base commences. There is, moreover, something scrappy and incongruous about the decoration of this portion. The foliated work in the slope looks out of scale, and seems to have little reference to the space it occupies and still less to do with any other part; and the decoration of the legs does not strike us as being at all happy. The leaf-work ornamentation of the fall-front to upper part is more pleasing in design, and the execution of the inlay is remarkably good. We are far from discountenancing any endeavour to break away from the commonplace; but novelty does not necessarily mean eccentricity, and we must say that a piece of furniture, however original, should express somewhat the purpose for which it is intended.

The Settle, designed and painted by Mr. Walter Crane and made by Mr. Edward Miles, contains some good points, and certainly both by design and verse announces unmistakably the object for which it was made. The quaint lines in the panels are a happy idea, and the general outline and division of parts is good. We, however, take decided exception to the two pilasters in the back being finished with small projecting caps, which support nothing and end very unfortunately below the moulding; also to the way the curve of the two end brackets becomes, for part of its outline, completely lost in the line of the upright piece by becoming perfectly flush; this surely could not have been intended so. We would point out also that, except for children, the seat is too low for comfort; and the whole thing is rather dwarfish and slight, and does not promise to survive the wear and tear of many years. It is enamelled white, with painted ornamentation of a reddish brown.

## CHIPS.

The Dover Harbour Board have decided to expend £20,000 to further develop the docks, with a view to improve the capabilities of the port for trade purposes. Large warehouses, for the reception of grain and other cargoes, are to be erected on the quays.

A meeting of the Parisian artists who separated themselves from the old Artists' Association was held on Saturday night at the house of M. Meissonier, their chief, when the statutes were approved of a new society, which is to be called the Société Nationale des Beaux Arts.

The rural sanitary authority of Conway adopted, on Friday, a scheme by Mr. Farrington, C.E., for the sewerage of Penrhynside at an estimated cost of £850. At the same meeting it was reported that the Local Government Board had sanctioned a loan of £1,250 for sewerage and water purposes at Llysfaen. It was agreed that these works, for which Mr. Farrington is also the engineer, should be forthwith started.

A special service was held on Friday at St. Cuthbert's Church, Newcastle-on-Tyne, to celebrate the completion of the reredos. It is in the form of a triptych, with folding doors, which are closed in penitential seasons. When open the pictures represent joyful events in the life of Christ, and when closed the mournful incidents. The central panels represent the institution of the Holy Communion and the Transfiguration. The carved work is in limetree wood, the canopies are gilded, and over all is a representation of the Crucifixion. The whole is designed by Mr. W. Searle Hicks, of Grainger-street, Newcastle.

The new ring of six bells which has been presented to St. Leonard's Church, Sandridge, Herts, as a memorial, at a cost of £180, was dedicated on Friday afternoon. The new bells were founded by Messrs. Warner and Sons, of Cripplegate, London, and the tenor weighs about 10cwt.

The Rhondda Valley and Swansea Bay Railway is approaching completion. The contractors are Messrs. Lucas and Aird, whose tender has just been accepted at £25,000 for the construction of a pier at the Mumbles, and a line of railway from that place to Swansea.

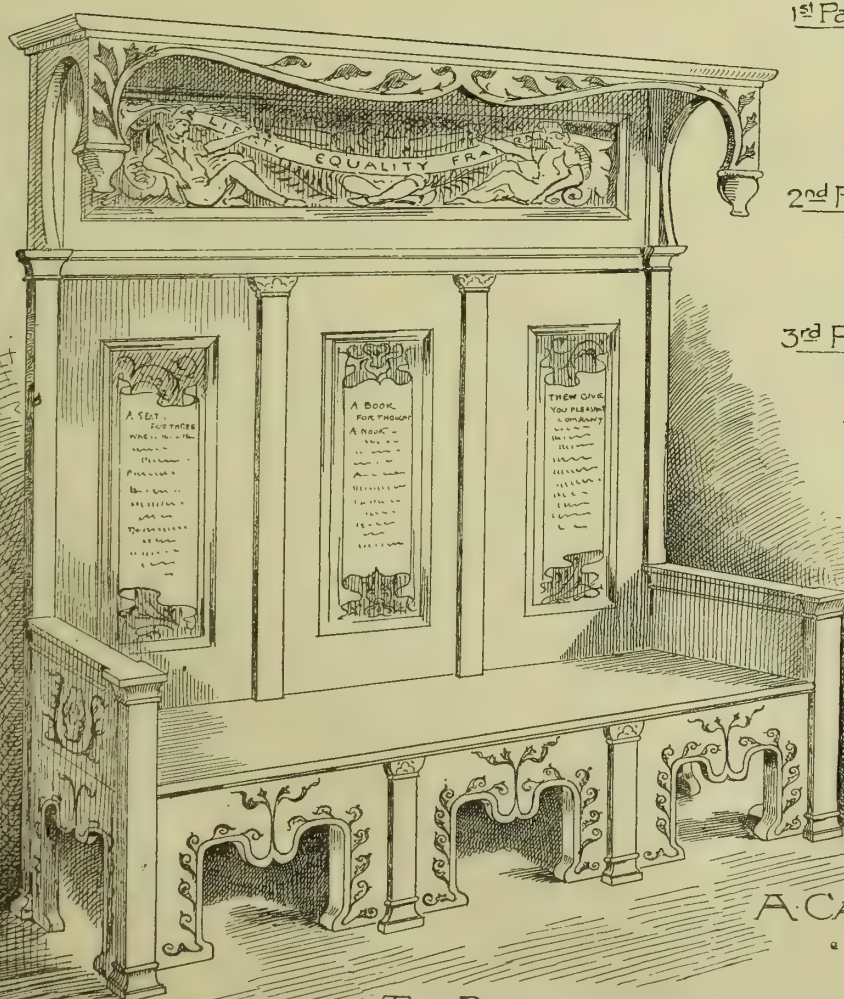

The new school of art in Warwick-street, Leamington, was formally opened on Saturday by the Countess of Warwick.

INLAID WRITING TABLE (WITH FALL DOWN FRONT)

DESIGNED BY G JACK EXECUTED BY MORRIS & CO

1<sup>st</sup> Panel

A Seat for Three,  
Where Host & Guest  
May side by side  
Pass toast or Jest;  
And be their number two or three  
With elbow-room & Liberty  
What need to wander East or West?

2<sup>nd</sup> Panel

A Book for thought,  
A Nook for rest.  
And meet for fasting or for fest  
In fair & equal parts to be  
A Seat for Three.

3<sup>rd</sup> Panel

Then give you pleasant company,  
For youth or elder shady tree,  
A roof for Council or Sequest;  
A corner in a homely nest;  
Free Equal & Fraternally,  
A Seat for Three.

A CANOPIED SETTLE  
BY WALTER CRANE

TWO PIECES OF FURNITURE AT THE NEW GALLERY  
REGENT ST (ARTS & CRAFTS EXHIBITION)

## WAYSIDE NOTES.

THE vast amount of unremunerative labour elicited from architects by the Sheffield competition has evidently left a deep impression upon the mind of the assessor. The Alpha and Omega of the address which Mr. Waterhouse delivered at the Institute on Monday evening last had for their burden an earnest hopefulness—unmistakably the outcome of feeling—that a day may dawn when the vitality of the architectural profession may not be so insidiously sapped by the system of competing that pertains at the present time. And one can scarcely exhibit surprise that an experienced assessor should thus deplore the wastefulness of competitions. Having, previous to an inspection of the drawings, his own notion as to due relation between labour and hire in respect to the proposed work, and coming suddenly upon broad acres of careful design and draughtsmanship, such a one must grieve at the sight presented, and moralise thereon in no happy strain. An assessor, moreover, is the only person connected with a competition who obtains a comprehensive idea of the amount of work involved in the preparation of the designs and drawings. Furthermore, one who, like Mr. Waterhouse, goes from competition to competition in the capacity of a judge must have a memory of these broad acres of draughtsmanship that does not trouble the conscience of the ordinary individual, and it is scarcely a marvel that he should express fervent hopes that a brighter day may dawn, when gratuitous designing of this kind shall be unknown.

Mr. Waterhouse's condemnation of alternative schemes in competition work is to be noted as confirming an opinion often expressed in these columns, that alternative scheming is a sure and certain evidence of a vacillating disposition, unformed opinions, and an ineffectual grasp of the problem at issue. And, says the old proverb, "Between two stools we come to the ground." It would show ingenuity on the part of an architect if he arranged his stretchers so that by pulling strings the drawings would suddenly flap out, like a Christmas-card, and exhibit various alternative designs: thus, pull the top string, and we have "Design for proposed town hall, Pettytweddleum"; pull bottom string, and we have "Ditto, do., without tower"; and pull side strings, and we have respectively, "Ditto, do., showing the same in the Neo-Greek style," and "in the Anglo-Low-German-Queen-Anno-Norman-Shaw-Ernest-George-O! style of architecture"! It would be ingenious, but not likely to obtain for its inventor the coveted job of building the P. Town Hall.

I was sorry to hear from a friend who attended the address to students that the attendance was very poor, both on the part of members and students, and there was little enthusiasm at the meeting. I do not know whether there were, as on the last prize-distribution at the Institute, many absentees amongst the prize-winners; but one might have thought common courtesy and the demands of ordinary etiquette would have prevented a similar occurrence on this occasion. Had it been generally known that the President of the R.I.B.A. was to address the meeting on the subject of competitions, I don't think that there would have been standing-room in the Council-chamber, unless the bulk of the profession are remarkable for sloth and inertness, and too apathetic to take advantage of any opportunities that may open to them. Young architects do not get a chance of hearing practical advice on competing and competitions from Mr. Waterhouse every day of their lives, or on any architectural matter, so far as that goes. But, judging from my friend's description of the meeting, these gentlemen are so busily engaged that they could not find time to attend. I am glad things are so prosperous.

For my own part I have enjoyed reading the address *in extenso*. Mr. Waterhouse said, in conclusion, that he had been addressing students; but in his remarks there was a kind of practical information for any architect. Perhaps that *bête noire*, the porte-cochère, did not get any nearer being killed than heretofore; but the hints given on its design are the result of long experience. If the remarks as to the absurd binding down of competitors to ridiculous restrictions have some weight with the inaugurators of competitions, we shall all be

glad. It would indeed be well if, instead of seeking to instruct, corporate bodies and other would-be clients would endeavour to obtain ideas from architects. The folly of specifying the exact sizes of insignificant private apartments, I place on a level with that of the German students who work out theoretically calculations for machinery, &c., to three places of decimals, a process which the most insignificant inadvertence in practice renders a mere vanity.

Most unreasonable of the many unreasonable wants in connection with the architecture of to-day is the desire for a *new style*. It is a desire the futility of which, one would have thought, was amply demonstrated by thoughtful lecturers and writers years and years ago. The hankering, however, after this "new style" breaks out afresh now and again. I do not think that Mr. Alfred Darbyshire really wants this new style; but, whether he does or not, one might be pardoned for supposing that the former is the correct interpretation of a sentiment expressed in his recent lecture at Manchester. Anyhow, the cry was taken up by the lay Press. A new style! a new style! My kingdom for a new style!! If anyone came to me for a new style I would supply him with one—he wouldn't want another! I would begin building with a cornice and carry above a reversed order of columns, finishing with the plinth, turning every moulding inside out, and do, in fact, anything novel and unlike any decent bit of architecture in the old or new world, either now existing or that "used to was." Any client dissatisfied with his architect, and desiring a brand new style, can apply to the ancient "Goth" for the same, which will be supplied on the shortest notice. No money, however, returned if not approved, as it is believed that the new style might not turn out such a boon and a blessing as some imagine.

"The fact is," said the *Globe* last week, when commenting on Mr. Darbyshire's lecture, "the fact is that we are still in want of a distinctively modern style of architecture." Quite the contrary! The fact is, as many know, we have too much in our latter-day architecture that is distinctively modern in style.

At the root of this "new style" fallacy is a failure to perceive that new style is a *growth*—a slow development, insensible in time present, but appreciable in a retrospect over centuries. No one conversant with a mere outline of architectural history will believe that a new style can be evolved either by an effort of genius or by a "fortuitous concurrence of atoms"—in other words, by chance. Many persons, however, do imagine that a new style of architecture can be made like a new hat, or invented, as one would invent a patent bottle-stopper. It should be plain to those with the smallest knowledge of what constitutes true architecture that attempts in this direction only produce abortions. The most superficial analysis of a design for a new style in this manner would show that it was composed of an incongruous piling-up of forms and features, common to as many different styles as were familiar to the designer.

Perhaps the nearest solution of this new-style problem—if one can pretend to solve a problem which, from its nature, is evidently resolvable only by time itself—would be to get 10,000 men worthy of the name of architects to assist in designing a certain building to fulfil certain stated conditions, each architect binding himself to use only such material as is most adapted to the purpose, and in harmony with the requirements of the age, and undertaking to employ no method of construction, or manner of design, for the sake of mere association. Furthermore, they must employ no method of ornamentation but such as is, first, of intrinsic beauty, and, secondly, adapted to its peculiar purpose. If one of the cravers after a new style could find 10,000 men of the description given, and would employ them to consider this one building for, say, ten years, he might, by the expiration of the year 1899, become the proud possessor of a structure that should be as nearly as possible in the true architectural style of the 20th century. Whether he would think well of the style would remain to be seen.

I have no faith in the practical style-evolver, who says a church should be built of iron and cement-concrete. Nor, on the other hand, do I

believe that mere outward and visible form has anything to do with true style, which is rather dependent upon an inward and spiritual grace. The former is engineering as distinct from that architecture which "proposes an effect on the human mind, not merely a service to the human frame"; and as regards the limitation of old forms and features, I have long held the opinion that the true architectural style of to-day is one not based upon any single style of the past, however good, but upon a study of old styles. Certain it is that if anything has been done, and is to be done, to formulate a Victorian style of architecture, it has been, and will only be, by a catholic study—in a spirit that appreciates the true and beautiful, and abhors the false and debased—of all past styles. GOTH.

## CHIPS.

A new peal of six bells, cast and hung by Messrs. Warner and Son, of 6, Cripplegate, were dedicated at Holy Trinity Church, Bicton, Salop, last week.

An extension of the schools connected with the David Thomas Memorial Church, Bishopston, Bristol, is about to be carried out at an expenditure of £1,300. The new hall will have an open-timbered roof, and will accommodate 600 persons. On the ground floor, and approached by side gallery, there will be two tiers of class rooms. The end gallery will seat about 100, and the space underneath will be inclosed with revolving shutters. The large hall will be fitted with a rostrum. The work will be of a simple Gothic type, agreeing with the church building. The contract has been taken by Messrs. R. Wilkins and Son, of Surrey-street, Bristol, for £1,185; the work will be executed under the superintendence of Mr. Alfred Harford, Broad-street, Bristol.

The banqueting hall of Carlisle Castle, which was used as military orderly-rooms and clothing depot, was on Saturday destroyed by fire, which originated at the pay office. A large quantity of regimental stores and records and the colours of one of the Militia regiments were burned. The hall thus gutted formed part of an Edwardian palace in which Parliaments were held in the reign of Edward I., and communicated with the chapel and tower in which Mary Queen of Scots resided or was imprisoned during her sojourn in Carlisle.

The windows of the north transept at St. Andrew's Church, Conover, which have been filled with stained glass of a character to accord with the Norman period of the stonework, were recently dedicated. The left-hand window contains, in a medallion form, the figure of St. Peter, with his keys; and the other the figure of St. Andrew, with his Saltire cross.

The monthly meeting of the Bristol Society of Architects was held at the Fine Arts Academy, Clifton, on Monday week. Mr. Thomas S. Pope in the chair. A paper, entitled "Architect, Client, and Builder," was read by Mr. W. E. Jones, followed by a discussion, which was joined in by the chairman and Messrs. W. L. Bernard (hon. sec.), W. V. Gough, J. H. La Trobe, J. R. Lysaght, J. F. Wood (Fellows), and Messrs. H. W. Harding and W. S. Skinner (Associates).

The design by Messrs. J. Powell and Sons, of the Whitefriars Glass Works, London, has been accepted for the stained-glass windows to be placed in the Abbey Church, Romsey, as a memorial to the late Lord Mount-Temple. The windows, two in number, are each of three lights, and occupy the east end of the church. The outlay will be £800.

The Roman Catholic schools of St. Mungo, Glebe-street, Glasgow, have just been rebuilt on the site of older ones at a cost of £4,000. The schools are two stories in height, and accommodate 800 boys. The walling facing the streets is of red Dumfriesshire stone. Mr. Devlin, the contractor, has carried out the work under the superintendence of Brother John, of the Passionist Community of St. Mungo's. The plans were prepared by the Rev. Osmund Cooke, who had been an architect, and now is a Passionist stationed in Paris.

On Tuesday week a lecture under the auspices of the South Wales Art Society and Sketching Club was given at the society's club-room by Mr. W. Rönnfeldt (president of the Cardiff Naturalists' Society), on South Wales scenery. Mr. T. H. Thomas presided.

The scaffolding is being struck from the front of the new municipal buildings at Newcastle-under-Lyme, now in course of erection from designs by Messrs. Sugden and Blood and Messrs. Chapman and Snape, joint architects. Four emblematic statues, carved by Mr. J. J. Milson, of Manchester, from designs by Mr. B. Creswick, of Birmingham, have just been placed in position on the Iron Market front of the buildings; they are over life-size, carved in red Corsehill stone, and represent painting, music, literature, and architecture.

## "BUILDING NEWS" DESIGNING CLUB.

## A CEMETERY CHAPEL.

WE have chosen the designs of "Fiddler," "The Red Rover," and "Tyne" for the first, second, and third places in this competition. The following is the text of the instructions issued to members:—"A cemetery chapel for a Church of England burial-ground, with lodge for sexton adjoining. The building is to stand at the entrance of the graveyard by the side of the main central roadway into the grounds, and the entrance gates are to form part of the scheme. The chapel is to be 30ft. long inside, exclusive of altar space, which may be in a small chancel or apse. Width of chapel, 20ft. inside. Provide a vestry 10ft. square, with fireplace. At the west end over the entrance a small gallery, affording space for a choir of three men and three boys, as well as a small organ, is to be included, with an external stair turret leading to same from vestry. Put a simple bell turret; chapel to be warmed with hot-water radiators. Lodge to comprise sitting-room (14 by 12), kitchen (10 by 12), scullery and offices, and two bedrooms. Style Geometrical Gothic, materials stone and brick, roof tiles, pair of gates of wood hung on stone piers 10ft. apart. Put a small gate 4ft. wide on one side next lodge. Scale 8ft. to the inch. Plans, two elevations, section, and sketch." The first two designs are illustrated to-day, and it will thus be seen how the winners in the contest have worked out the problem. We are perfectly well aware that neither of their designs are perfect, and it is not unlikely that those who have friends amongst the competitors may think other designs in which they are interested more worthy of selection. This is inevitable in every competition, and correspondents are reminded that we have had the advantage of seeing all the plans sent in, every one of which has had due consideration.

"Fiddler" overstates the importance of his design in scale and proportions by the perspective sketch which figures in the centre of his sheet, making it look too big and too much like a church. Tricks of this kind are too evident to be actually misleading to technical readers and judges; but it is quite possible that the author himself may be deceived by his own figment. The design in execution would not look half the size indicated by this sketch, and the fault which we note chiefly in the design is intensified by this perspective. The idea embodied in the facade seems to belong to a much larger structure, the narthex-like porch and the turret staircase tower leading on to the transept, occupied as a vestry, make up a composition better adapted to the west front of an ordinary church, though by reason of the breadth and simplicity of the parts introduced, "Fiddler" has avoided the faults conspicuous in other less dignified designs, for, at any rate, his chapel is neither fussy nor toy-like in general effect. In point of fact there are few buildings of any class throughout the country more unsatisfactory in their design than cemetery chapels. They are either cold, bald, and hideous, or overdone with trivial details and meaningless features as florid as you like, generally done in Bath stone and Kentish rag, while for the style "Gothic" is not the word for it. "Fiddler's" design avoids these failings, and gives us an equally unassuming cottage or lodge; and who shall describe the horrors to be seen any day in the way of lodges to cemeteries? In his plan "Fiddler" has overlooked one point, and that is the altar, for in a Church of England burial chapel an altar is necessary, and the reading pew for the priest should be placed on one side if such a convenience is provided. A sacrum without an altar is meaningless; but it is only an oversight in detail of which we complain, seeing that the chancel with an altar space is provided. The way to the vestry cuts into the seating room needlessly—a fault avoided by "Red Rover." The direct entrance is good, and the tier space seems suitable. No plan of the gallery is given. The lodge plan is fairly convenient, though the doors open awkwardly on to the fireplaces both upstairs and down. The entrance gates and piers are simple and in keeping with the buildings. The position of the hot-water radiators is not indicated on the chapel plan, as they should have been. "The Red Rover" draws his studies in too rough and patchy a style, making them look flash and overdone. We have quieted them down in the little reproduction given herewith. He will understand what we mean, and will

see how unsatisfactory the perspective sketch is. The chapel itself is more ordinary, and the apse is a mistake, tending to cut up a small building without materially increasing its utility. The arcaded interior narthex under the gallery is too ambitious, and the porch is out of proportion to the main building. The staircase lights in the turret are too numerous for exterior effect, and if light be insisted on as the reason, then it would have been better to put a row of lights in one place horizontally instead of raking them up in this fashion on every face. The turret itself is too conspicuous, and we prefer a simpler treatment for the bell. The side windows to the chapel are pretty, but do not accord with lancet lights at the west end. "Tyne" bids fair to be a somewhat original designer, and clearly has endeavoured to avoid the stereotyped style of Burial Board architecture. He falls, however, into other errors almost equally objectionable in his desire to secure a freshness of feature. Thus two ugly thin and deeply projecting buttresses break forward from his western gable over the vestibule and gallery above it, and support a bell between them on a beam 6ft. or so long. In elevation the effect is not so bad, but in perspective the crudity of the device is most conspicuous. The high-shouldered gallery walls, too, with the lights crowded up to the ceiling level, are very ugly. As to the plan, no space is left for the tier inside the chapel, and the doors are so badly placed as to render it almost impossible to get a body in. Outside the chapel a sort of mortuary is provided, marked "Space for Bier," so that we presume "Tyne" intends that the body is to stand in this adjacent building while the funeral service is going on inside the chapel—a proposal which, of course, is quite contrary to the Church of England form of service. The semicircular arch to the bay of the lodge is very ugly, and the perspective sketch is not good. The bathroom in the lodge was not asked for, and it is absurdly narrow and inconvenient. "Wallaby" adopts a fairly pure type of architecture, though the horseshoe-like American semicircular arches to the lodge front are out of keeping and scale with the rest of the work. His plan, notwithstanding the ugly apse, which, to make it worse, is stone-groined, may be said to fairly answer its purpose, though in points of detail grave faults can be found, as, for example, the ladder-way down from the gallery, or the reckless manner in which the living-room and kitchen doors are arranged. There are five doors in the kitchen, two windows, and a fireplace. The parlour is nearly as bad. This competitor takes great pains with his drawings, and will improve if he goes on trying, for he is a good worker. Our remark may seem somewhat invidious, seeing that so many contributors are equally worthy of praise, and we wish to acknowledge industry all round. "Myth" deserves commendation, but he is too fond of florid detail, and his carriage porch, necessarily a big feature, is made needlessly large and out of scale with the rest of the building by the great solid gable over the grand arch. The chapel plan is very singular, being L-shaped, or rather square, with the altar and "chancel"—called here an "apse"—carried out on one side in the far angle. The arrangement is radically wrong, and anything but effective. A perspective is wanting again. "North Star" is always worthy of note, but never so good as we could wish, which is the more to be regretted because there is so much merit in his work. The architectural features of his design this time look thin, an effect heightened by his drawings, and the importance of the chapel is lessened by the altar space being carried out like a miniature chancel, instead of keeping one ridge line for the roof and width for the plan from end to end. The verandah along the front is not a bad feature, and the lodge rooms are contrived all on one floor. His architecture is fairly good, but a section is wanting to show how the gallery and roof were to have been managed. "Niger" is next best, but he intends to leave the corpse in the porch during the service, and shows it so, providing no room inside. The first of his thoughts seem to have been devoted to the gallery, and how to invent a solid-looking and fetching sort of front to it, dodging in a central pier in the plan, and squeezing in the staircase up to it outside under the buttress, which helps to carry the bell turret. He forgets to show where the organ is to stand, and avoids points of this kind by giving no gallery plan. "Syak" seems to deserve the next position; but we do not like his plan with two doorways—they are so

meaningless and so inconvenient, while very little space is left for the coffin to stand in. The vestry door is too public, and the stair turret up to the gallery is too small. The general effect of this design is not a happy one. "West Anglian" has a much more practical plan, which he shows with care, sparing no pains to do it justice, view, block plan, and all complete. These are important points of merit in his favour. We do not like his architecture; it is so all-overish, no breadth anywhere, though we are bound to say that the building is quite equal to the general run of such buildings. "Bunya" in not a few points corresponds with the last-named, though he gives us an apsidal-ended chapel, and crowds up the space with seats for mourners, so that the front row would look on to the coffin, leaving no room whatever for the bearers. On the whole, he is not so good as "West Anglian," but his perspective view is better perhaps. "Signum" delights in florid work, and draws it out in brown without much care, his tracery being very faulty. There is something, however, in his design which shows ability and ingenuity, which on another occasion may be more successful. "Streona" has greatly improved if this be the same competitor as before has used this motto. His plan is practical, and his section is good, with the radiators shown on in the former, and a boiler space under the vestry. The exterior treatment affords little to complain of, even if we are unable to describe it as very good—indeed, if the truth must be told, it savours of the commonplace. "A. G." in a circle deserves the same remark; but his plan is not so good as the last. The door at the side and the regulation chancel spoil it, while the relative positions of the lodge and the chapel are unfortunate, and look crowded without any reason. The perspective is nearly a good drawing, and it shows care. "Nox" draws in a gingerly fashion and with a flash effect. His elevation would look better in execution, though we cannot say we admire it. The plan is not so bad, in spite of points of detail wanting in study. There is no w.c. for the use of the chaplain, which clearly is an oversight. "Red Rover" failed, too, in this respect. "Lord G." has a curious notion of the fitness of things, and this design is quite "Grimthorpean" by reason of its incongruity. The wheel-like windows along the side are ugly, and the extinguisher-capped bell-turret is also ugly, likewise the semicircular apse. The gallery front is not objectionable, and the drawings show considerable merit, as well as an endeavour to draw with spirit, if not good taste. "Dr. Jekyll" makes his sheets too inky, and back-lines too much. His chapel would be very dark with no side windows: otherwise the plan is rather a good one. The lodge plan is very cramped and poor. The bird's-eye view of the chapel is too big, though it is evident "Dr. J." will do better another time. "Renaissance" brings us down to the regulation sort of cemetery chapel, with arcaded rows of lights, low side windows, lofty high-pitched roofs, apsidal chancels, and pierced buttresses. Why not study a better type of work than this? The author ought to do more satisfactory work, for his view is rather well delineated. "Multum in Parvo" does strike out with the idea evidently of arriving at something fresh, but he fails in fitness and proportion. The fenestration of the chapel is very ungainly and ill-arranged. "So and So" intends also to do a new thing, and in a way succeeds. For the present we must ask him to try again. "Coaly Tyne" draws his perspective badly: careless is not the word, but his plan shows originality and some study. "Skull and Cross Bones" sends rather a pleasing south elevation with an archway porch connecting the chapel with the lodge, and a very grand castle-like gateway outside with piers like keep towers. The plan is not better nor worse than many more. "I Try": we are sure of it; only try again. "Sarchedon" gives us a fairly good group, but the chapel looks pinched up and over-windowed. The front elevation is the best. "K. W. T." is the next design, with a plan over which some care has been taken, the radiators being shown, and the chapel is seated properly. The little chancel is ugly enough, and we think the vestry very cramped. "Argus" follows with a neatly-drawn sheet, having a chapel with too many doors at the west end. The architecture shown is fairly good of its kind, which we cannot say of the design by "Glaucus," whose plan is equally poor. The other designs

are thus arranged in order of merit:—"Menelaus," "Paul Jones," "Coverac," "Y" in a circle, "Dot," "First Attempt," "A" in a circle, "Mac," "Vyrawy," "Country Bumpkin," "Reference," "Q. E. D.," and "Corinthian."

#### THE EXAMINATION IN ARCHITECTURE.

THE fortnightly meeting of the Architectural Association was held on Friday evening, Mr. Leonard Stokes, the President, in the chair.

An exhaustive paper was read by Mr. Arthur Cates, Vice-President R.I.B.A., on "Examination in Architecture in the Past, the Present, and the Future," as an introduction to a discussion on the subject. Mr. Cates explained that much discussion on the desirability or otherwise of establishing a diploma for architects took place in France in 1854 and 1855, and the subject was brought before the members of the A.A. in the latter year by the late Mr. J. H. Chamberlain, of Birmingham, and Mr. Alfred Bailey, the president for that year. A memorial from the Association was subsequently presented to the Royal Institute of British Architects asking for the "establishment of an examination which should eventually serve as the basis for the issue of such a diploma as should certify that the holder thereof was fully qualified to practise as an architect." It was not, however, till June, 1860, that the Institute decided in favour of the establishment of a voluntary examination, and this came into force two years later. This voluntary examination was in force for 19 years—from the beginning of 1863 till 1881, during which period 47 candidates passed the preliminary examination, 37 the proficiency examination, and 3—R. R. Baynes, R. Phené Spiers, and T. H. Watson—the Class of Distinction. This voluntary examination did not satisfy the requirements of the day, and gradually failed to command any interest in the student class. In 1877 the R.I.B.A. decided that after May, 1881, all persons elected as Associates should be required to pass an examination before their election. Since March, 1882, fourteen qualifying examinations had been held in London, two in Manchester, and one each in Glasgow, Leeds, and Liverpool—nineteen examinations in all. At these examinations 310 candidates had passed, and twenty-three relegated to their studies were entitled to come up again without further payment. Thus, in nineteen years (1863-81) the number of candidates passed in the voluntary examination class of proficiency was only thirty-seven. In eight years (1882-89) the numbers passed in the obligatory examination were 310. The number of candidates who passed in each year was: 1882 twenty-one, 1883 nine, 1884 twenty-one, 1885 seventeen, 1886 thirty-nine, 1887 forty-four, 1888 eighty, 1889 seventy-nine. The steady increase, as the examination had become better known and appreciated, was most satisfactory. The system of relegation, by which candidates who, while not failing entirely, had not succeeded in obtaining a sufficient number of marks to pass, were permitted to come up at a future examination, either for the whole, or for that particular section in which they had failed to satisfy the examiners, had been most successful, and so advantageous to the candidates that it will be continued in the progressive examinations recently established. Until the "final" of the progressive examinations comes into force, in not less than three years' time, the qualifying examination as at present conducted will be continued. The experience gained in the past eight years, much conference with the younger candidates, and careful study of the answers to the questions set, made it evident that in the interests of the students it would be desirable to establish a more elementary examination, which would secure that they were well grounded in the first principles of the subjects to be dealt with before proceeding to more advanced studies. In May, 1887, at the meeting of the General Conference of Architects on "Education," after the reading and discussion of various papers tending to this end, the following resolutions were unanimously adopted: "1. That it is desirable that the guidance and direction of the education of those entering the architectural profession should be undertaken by the Royal Institute of British Architects. 2. That to realise this end the Institute should prepare a scheme of a complete system of examination. 3. That such system should comprise: 1st, Preliminary, for

pupils entering the profession, as a test of general knowledge—those passing this to be 'Probationers R.I.B.A.' 2nd, Intermediate, for pupils in their third year or earlier, for the general principles of art and construction—those passing this to be 'Students R.I.B.A.' 3rd, Final, pass examination to qualify for A.R.I.B.A., at 23 years of age or earlier." The three resolutions having been referred to the Council, the Institute, by resolutions passed 8th April, 1889, established a system of progressive examinations: 1. Preliminary; 2. Intermediate; 3. Final or Qualifying. The preliminary examination was to test the general knowledge of aspirants entering, or who had just entered, the profession. The first preliminary was held in November last, and was satisfactory. Out of 107 candidates who were admitted, 44 were declared exempt, 43 passed, and 23 were relegated to their studies. The programme of subjects included in the examination was very clear; they were all of a simple elementary character, but some of the candidates appeared to have thought it unnecessary to trouble themselves to acquire any accurate knowledge on some of the subjects, and in consequence were sent back. When well-established, this preliminary examination would, he believed, influence the concluding portion of the school education of youths destined to enter the profession, and thus prepare them with a good foundation for their further studies. The probationers now registered would in not less than two years, on submitting satisfactory "testimonies of study," be admitted to the intermediate examination, the successful passing of which would qualify the student for registration as a student R.I.B.A. Not less than two years after having passed the intermediate, the student would be admitted to the final examination, to qualify for candidature as Associate of R.I.B.A. This final examination would cover very much the same ground as the present examination in architecture; but with the preliminary training necessitated by the intermediate examination, the results, so far as regards the attainments of the candidates, would probably be even more satisfactory than at present. Some adequate provision would for a few years be made to meet the cases of architects in practice, whom it would not be reasonable to require to pass the two previous examinations, and from whom it would be equally unreasonable to require full testimonies of study. The details of the programme of the progressive examinations had been arranged with a desire that the student, in whatever part of the country he might be, should be guided in a sound course of study; but should be left quite free as to the sources from which he might obtain his knowledge, all baneful academical influences being avoided, and the natural abilities and proclivities of the student allowed free play, consistent with the acquisition of sound elementary knowledge. The lines on which the programme had been founded had been indicated by the deficiencies in elementary knowledge evinced by candidates at the obligatory examination. It was, therefore, hoped that students following this course with care would lay a sound foundation for those more advanced studies required to secure a pass in the final. The work set out for the aspirant to enable him to pass the intermediate might appear formidable on paper, but really did not demand any particular exertion from an ordinary student. Continuous and well-directed application by home or class study after office hours would be essential to attain success; but much, especially the completed testimonies of study and the necessary preliminary work, should be carried out in the office, under the eye of the architect master. Such master would greatly benefit by the improved intelligence of the pupil and the more advanced knowledge he brought to bear on the active work of the office, and might be rewarded for the loss of the services of such pupil as an office-help by the conviction that he was in some degree fulfilling the obligation he undertook when he accepted the responsibility of taking the future of the pupil into his hands.

Mr. J. A. GORCH proposed a vote of thanks to Mr. Cates for his valuable paper, remarking that no greater service could be rendered to young men entering the profession than to put such a paper as that just read into their hands, showing what they would be required to learn. Mr. Cates would admit, with him, that the present examination was not all that was required; but he trusted that the experience gained by the board of examiners would enable them to evolve

some still better system in the future. He entirely agreed with Mr. Cates that principals should afford facilities to pupils to prepare for passing the examinations, and further thought that opportunities ought to be given students for acquiring a knowledge of their profession other than that provided in the office. As for assistants, but little compulsion would be needed to induce them to enter into examinations, as their feeling was to go in for every opportunity of improvement that presented itself.

Mr. H. D. APPLETON, ex-president, seconded the motion of thanks. A great difficulty in the way of bringing students together in small provincial towns was the extreme jealousy country architects had lest their pupils should come in contact with those in other men's offices. He thought, however, this was a groundless fear, for students had too much *esprit de corps* to allow information as to what went on in their office leaking out; but the feeling among country architects undoubtedly stood in the way of the formation of branch associations in the smaller towns. Another difficulty which the Association met with in endeavouring to affiliate with itself provincial branches was that many of these preferred to be federated, if at all, with the Institute. Nevertheless, he believed something might be done in this way. He criticised in detail some of the subjects set at the preliminary examinations, remarking that the student was expected to make too many sketches of the Orders, for instance, in the time allowed.

Mr. JOHN SLATER said a committee of the Institute had come to certain conclusions as to the examinations, which could not be stated until they had been put before that body. Some candidates had in the past supposed that they could entirely ignore one or more of the subjects named for the preliminary examination. If an impression existed that they could evade some subjects by doing well in others he wished to correct it, as candidates must undergo examination in all the subjects named. A very great deal of the success of a pupil at the preliminary, and, indeed, subsequent, examinations depended on the influence of his employer, and he, therefore, held with Mr. Gorch, that it was absolutely essential for the pupil's principal to give his student time in office hours for preparation; but this being conceded, all would be in vain, unless the student made a stern individual effort to succeed. He was sorry to hear Mr. Appleton state that so much professional jealousy existed in country towns lest assistants and pupils should meet together; it was a short-sighted policy on the part of principals to discourage mutual intercourse between assistants, for it must tend to benefit young men all round to discuss questions of practice together.

Mr. H. O. CRESSWELL regarded the examination scheme set forth by Mr. Cates as eminently satisfactory, and thought the Association could with confidence leave it in the hands of the Institute. But they had to consider the question of education, and if they were as a body to continue the education of students, they ought to be backed up by the Institute. If afternoon classes were recommended by the committee, it was to be hoped that the council and members of the Institute would exercise their influence in the direction of getting principals to allow their pupils to attend them during office hours.

Mr. A. BERESFORD PIRE referred to all that had been done by Mr. Cates to establish and insure the success of the examination system, but added that, in his opinion, the great mistake of the system had been the exaltation of the Institute rather than to fit a man to become a good architect. The aim should be to awaken enthusiasm, to seek to kindle the divine afflatus in the student, and not to offer, as the main inducement to pass, to append certain letters to the student's name. Enthusiasm was the quality which ought to be expected of the student; but there were few traces of enthusiasm in the programme before them. It was possible to develop the natural faculties of the student, and to train him in the analysis of the beauties of such a building as the Parthenon, and this should be the aim of the examination, and not merely to inquire into the exact number of its columns, their height and distance from each other, and the minute measurements of the steps and doors. The student should as early as possible set to work at measuring buildings, instead of deferring this training till the last, for instruction in detail drawing was most essential to the future architect. The effect of drawing moulding

quarter full-size only, as required for the Institute examination, was disastrous to the learner. Mr. Pite criticised many features of the programme in detail.

Mr. W. MILLARD thought a scheme of education should have preceded the establishment of an examination system. The Institute had shirked its duty of educating the pupil; but the time seemed to be coming when the Association would not be able to continue unaided its amateur attempt at voluntary teaching. He thought a great reform in the examination would be to place candidates in the order of merit, instead of arranging the names of successful men in alphabetical order; they ought to be able to distinguish between those who just satisfied the examiners and those who came out highest. Such a classification would be an encouragement to students to acquit themselves well.

Mr. R. NEEDHAM WILSON concurred in the last speaker's remarks as to the desirability of substituting a list of candidates arranged in order of merit for the present alphabetical one. At present there was no inducement to take high honours or to do otherwise than cram.

Mr. COLE A. ADAMS said no man in this country had done more to promote the interests of architectural students, and to advance architectural education in England, than had Mr. Cates, and they all rejoiced to see that he had almost recovered from his recent severe illness. Now that the examination scheme was fairly launched, it brought in its train the education of students. The advantages possessed by pupils in the present day were enormous compared with those of the past, and it lay with each individual to improve the present opportunities to the full. Still, the responsibility rested on the architect to train his pupil, and delicate moral pressure should be brought to bear by the Institute upon principals to grant all facilities for improvement. He thought that principals might make arrangements to allow their pupils to join afternoon classes, if these could be established. As to the examinations, he was sorry Mr. Aitchison's proposals had not been adopted by the examining body, and he feared that the examinations dealt rather with mere names and dates, which were less to an architect than the practical knowledge of how to design a building. Mr. Appleton had referred to the difficulties pupils in provincial towns met with, owing to the obstacles put in the way of meeting each other by some principals, and by the absence of that mutual contact by which enthusiasm was evoked. Possibly if some such plan could be adopted in the profession as that which prevailed among solicitors, by which the pupils of country architects could be transferred for a period to the offices of London "agents," where they could enjoy the advantages of the Association classes and common room, the difficulty would be overcome.

Mr. T. M. RICKMAN, as one of those who helped to draw up the memorial of 1855, congratulated Mr. Cates on the success of the examination movement. Those who prepared that manual were not students, but assistants and clerks to architects, and books were not then so numerous as now. If the young men would come forward for the examination they might rely on the older ones to do all they could to assist them.

Mr. ARTHUR EARLE considered that the time had arrived when the Association should resolve itself into a regular school of training for architectural students, and suggested that if Mr. Cates could organise this departure he would have achieved a crowning point to his life, for which future students would be grateful.

Mr. T. W. GOLDSMITH criticised the examination scheme in detail, denying that it tended to the consideration of history, of dates and names, rather than of the art of construction. The Association was, he considered, no longer able to cope with the requirements of the day in education. In any reforms in architectural education, afternoon classes should be an essential part.

Mr. F. R. FARROW endorsed the suggestion that a classified list of those who passed the examinations, giving the marks gained, should be published.

Mr. CATES, in reply to the vote of thanks, which was carried amid applause, said the criticism which had been directed against the examination programme had been mainly directed against details. While he concurred in many of the suggestions made, he did not see how they were to introduce the element of "enthusiasm"

into an examination; but he had no doubt that the suggestions that had been received would have full consideration from the board of examiners. An examination could not be said either to discourage or encourage youthful enthusiasm. He regretted to hear of the professional jealousies existing in country towns, which prevented young men from meeting together, and he believed that if students would combine they would easily get all they wanted in this respect. Students must not look to the establishment of a college of architecture to carry them through difficulties; these could best be overcome by individual application, energy, and perseverance. He had not seen any instances of "cramming" in pupils prepared by the architects who prepared candidates for the examinations.

#### ARTIFICIAL ASPHALTE.

MANY attempts have been made to produce artificial asphalt with the hardness and toughness of the natural rock; but although some excellent substitutes have been obtained in the shape of tar pavement, no one seems to have hit upon anything cheaper and better than natural asphalt. Mr. J. Erslev, of Copenhagen, has, however, taken out letters patent for improvements in the manufacture of artificial asphalt, which are described as follows:—

Artificial asphalt, as is well known, cannot, as heretofore made, withstand great differences in temperature; for example, under the action of the sun it becomes soft and even liquid, while under the influence of cold it becomes brittle and cracks. For this reason it can only be used for floorings in places which are not submitted to extremes of temperature; but it cannot be used in the open air for pavements, streets, or roads, only natural asphalt being capable of standing the wear and weather. From a hygienic point of view asphalt-paving is an absolute protection, as it is not liable to harbour or develop bacilli, which are the cause of many epidemic diseases, and on this account alone it would be a great advantage if asphalt could be used instead of ordinary paving; but natural asphalt is so costly that it cannot be employed in all cases. After numerous experiments, the patentee says he has succeeded in producing an artificial asphalt which possesses all the good qualities of natural asphalt without its defects. According to his invention, he prepares artificial asphalt in the following manner:—

In a suitable metal pot he melts a mixture of coal-tar (*pyrooleum lithanthracis*) and resin (*resina pini flava*) in about the following proportions:—viz., 80 to 90 parts of resin to 20 to 10 parts of coal-tar. After the mass is thoroughly melted he mixes therewith 100 parts of pulverised sand or silicious earth or ordinary dry clay (argillaceous earth), or any other suitable finely-sifted earth or chalk, in a completely pulverised form, together with 200 to 400 parts of rough gravel. After the whole mass is melted together, it is formed into blocks in a mould, so as to facilitate transport. The asphalt thus prepared is employed in the same way as natural asphalt. It will be found to be absolutely proof against all temperatures as well as against blows. It will not yield under a heavy pressure or load, and it will not crack under a powerful blow; it will not be affected by hot water, and can be exposed to steam without affecting any change in its condition. Moreover the artificial asphalt makes better connection with the bed underneath it than natural asphalt, and thus prevents damp and water from lodging between the asphalt and the bed. The connection is nevertheless not strong enough to prevent the asphalt from being broken up without destroying the bed. It will withstand the action of acids, and will wear longer than natural asphalt. It is, therefore, evident that it is in every respect superior, as regards quality, to natural asphalt; it is besides much cheaper than any known paving material, and is only half the price of natural asphalt.

The annual meeting of the Yorkshire Centre of the National Association of Sanitary Inspectors was held in Leeds on Saturday, the president (Mr. T. Pridgin Teale, F.R.S.) in the chair. The medical officer of health for Leeds (Dr. J. S. Cameron) read a paper on "The Use and Abuse of Disinfectants." In the morning between forty and fifty members of the association had visited the Burmanoffs Potteries, the Corporation destructor, and the Leeds Sanitary Engineering Works.

## Building Intelligence.

SALFORD.—The new memorial pulpit in the Church of the Holy Name, Oxford-street, Salford, was inaugurated on Sunday. Rising from a base of white and blue veined marble, with thereon an upper base of alabaster (of which, except where superseded by marbles, the rest of the pulpit is composed), the pulpit rests on a series of black and gold alternating with black and white shafts, with moulded bases and carved capitals. The spaces are filled in with open panels of alabaster. Above the caps are two rows of flowing carvings. Slightly below the floor level are five pointed panels intended for mosaics, inclosed by pointed arches supported on columns of bluish stalactite and Irish green marble. The pulpit is approached by a flight of eight steps of Forest of Dean stone, the rises being filled in by deep red and gold coloured encaustic tiles. The balustrade is composed of alabaster arcading. The columns used here are of brocatella, sanguine jasper, and Iberian agate. The work is in the Decorated style. The pulpit is surmounted by an oak sounding-board, flat underneath. The work has been executed by Mr. A. B. Wall, sculptor, of Cheltenham, from the designs of Mr. J. S. Hansom, architect, South Kensington. Mr. Hansom's father was the builder of the church. The five panels of mosaic are intended to contain busts of five of the English martyrs of the Reformation, and of these two are in position.

#### COMPETITIONS.

CLECKHEATON.—We understand that in the limited competition among six architects for the new town hall at Cleckheaton, the design of Messrs. Mawson, of Bradford, has been selected.

MELBOURNE, AUSTRALIA.—A short time ago Mr. Howard Spensley invited competitive designs for enlarging the Royal Arcade, Bourke-street, by adding an annexe to run from Elizabeth-street, and joining the present arcade about the centre. A number of designs were submitted from the Colonies, and also from London; and, after careful consideration, the choice fell upon the design bearing the motto "Arcadia," which was awarded first premium, and was prepared by Mr. J. W. Lockwood, architect, of 472, Chancery-lane, Melbourne. The second premium fell to the lot of "Orient," by Mr. John E. Still, architect, of 50, Finsbury-square, London, E.C. It is intended to proceed with the erection of the building immediately.

NEWPORT, MON.—At Saturday's meeting of the Newport Board of Guardians the plans of Mr. B. Lawrence, signed "Economy," were accepted for the new House of Refuge. The cost is estimated at £1,900.

In our report last week of Mr. A. Fisher's paper on "British Art," read before the Society of Architects, the lecturer was made to say, on p. 89, near the foot of third column: "Out of every pound granted by Government for art education, 15s. is spent on its administration"; whereas it should have read: "Out of the amount granted by Government for art education the greater portion is spent on its administration." Our report was set up from advance proofs, and the attention of our representative at the lecture was not called to the modification.

A meeting of the heritors of Haddington parish was held on Saturday to consider the present state of the Abbey Church. The Earl of Wemyss presided. A report was submitted from Messrs. Hay and Henderson, architects, Edinburgh, in which it was stated that the church was not at present in a fitting state for public worship. Accompanying the report were plans embracing the partial and also the complete restoration of the Abbey. The restoration of the nave was estimated to cost £14,450, and this contemplated the removal of the present galleries. To provide the requisite number of sittings, it is proposed by the architects to renovate the transept, which would cost £6,500 additional. Plans were also submitted for the restoration of the chancel, at a cost of £12,000, the total estimated cost of the restoration being £22,750. The meeting agreed to print and circulate the report of the architects; but its consideration was delayed.

A new Congregational mission church to seat 360 persons is about to be erected in Hampton-road, Southport, from plans prepared by Mr. C. Sydney Ingham, of Manchester and Southport, at a cost of about £1,000.

# ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

**MANCHESTER ARCHITECTURAL ASSOCIATION.**—The last general meeting was held at the Diocesan Buildings on the 21st inst., Mr. J. H. Woodhouse, the president, in the chair. Mr. F. R. L. Edwards read a paper entitled "Prospective: a Twentieth-Century Architect." The paper was narrative in form, and showed a well-known outskirt of Manchester as a complete wreck, the result of the jerry-building demon's play. The "Twentieth-Century Architect" relates to a young aspirant; how nearly a century ago previous the younger architectural societies were sufficiently far-seeing to band themselves together after futile attempts were made to obtain legislation to restrain charlatans (who had crept into the profession somehow) from practising their dishonest work. The result of this movement was the foundation of what existed in that year of 1870—an architectural republic. It had obtained legislation and the confidence of the public, which the charlatans of the previous century had destroyed. The general council of the Republic controlled the architectural matters of the country, which had been formerly left in the hands of corporate bodies, who stuck tenaciously to useless by-laws. He then described the education of the student and workman of that century. Messrs. Mould, Hodgson, Hind, Stelfox, and Woodhouse criticised the paper.

**YORK ARCHITECTURAL ASSOCIATION.**—At the monthly meeting of this society, held on Thursday night, Mr. N. R. Yeomans in the chair, Mr. G. Benson, A.R.I.B.A., read a paper entitled "About Normandy," giving an account of a three weeks' ramble made by architectural students in that district. Leaving Southampton, St. Malo was first visited, then the picturesquely-situated Dinan, followed by Dol, which possesses a cathedral dedicated to St. Sampson, who, about the end of the 5th century, was Bishop of York, and subsequently went to Brittany, becoming Bishop of Dol, where he was buried. Avranches, Coutances, St. Lo, Bayeux, and Caen were all visited. Lisieux, with its half-timbered houses, offers great attractions to artists. The ancient houses, churches, and other edifices of Evreux, Rouen, and Nantes were also described. The lecture was illustrated by numerous photographs.

## CHIPS.

At a vestry meeting held at All Saints', Penarth, last week, plans by Mr. Coates Carter, of Cardiff, were adopted for a new church to be built on the site of the present one.

Dr. Schliemann, it will be recollected, recently offered to Capt. Bötticher to settle the discussion between them as to the real nature of the ruins at Hissarlik by a fresh examination on the spot. This examination took place in December, Dr. Schliemann being accompanied by Dr. Dörpfeld. There were also present, as arbitrators, Professor George Niemann, of the Vienna Academy, and Major Steffen, of the Prussian Artillery. During the examination, Capt. Bötticher withdrew his charge that Dr. Schliemann had tampered with the remains, and the two arbitrators have now signed a formal document to the effect that, in their opinion, the remains are not those of a necropolis, as alleged by Capt. Bötticher, but of an inhabited town, including a temple and halls.

The parish church of Salcombe, Devon, is about to be restored at a cost of £1,000, from plans and in accordance with a report by Mr. G. H. Fellowes Prynne, of London.

The engineer for the projected works of sewerage and water supply at Towyn, North Wales (Mr. Collingwood, of Rhyl), set the contractors to work last week. Mr. Morgan, contractor for the water, commenced at the reservoir, about three miles from Towyn, and Mr. John Jones began the sewerage works at Morfa Cadfan.

Plans for the extension of Warrington Infirmary, prepared by Mr. Williams Owen, of that town, have been provisionally adopted.

A new Masonic hall at Crediton, Devon, was opened on Friday. It is Domestic Gothic in character, is built of brick, with Bath stone dressings, and cost £750. Mr. Berry was the builder.

A wing, which is to serve for the present as chapel and school, has been opened at Providence Wesleyan Chapel, Queen's-road, Halifax. The new premises comprise a large assembly-room, eight classrooms, infants' room, newsroom, reading-room, &c. Mr. James Farrar, of Halifax, is the architect. It is intended to erect a large chapel on a site adjoining.

## TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

## TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 6d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 6d. (or 33fr. 30c.) To India (via Brindisi), £1 10s. 4d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 6d.

## ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph Advertisement inserted for less than 5s.

## SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING for TWENTY-FOUR WORDS, and Sixpence for every eight words after. All Situation Advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page advertisements and alterations in serial advertisements must reach the office by Tuesday Morning to secure insertion.

## NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XLII., XLVI., XLIX., L., LI., LIII., and LVI., may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—H. and K.—H. L. B.—T. L. and Son—B. B. and E.—G. E. H.—H. M.—B. F. S. Co.—J. S.

ENQUIRER.—(The trouble is a common one, due to draught. The most effective cure, and the cheapest, is a Boyle's chimney cowl.)

## "BUILDING NEWS" DESIGNING CLUB.

DRAWINGS RECEIVED.—"The Red Rover," "Cosmopolitan," "Cyclist," "Wallaby," "Skull and Cross Bones," "Dr. Jekyll," "Country Bumpkin," "Initium," "Fiddler," "P. R. G.," "Eth," "A" in a circle, "Mac," "Y" in a circle, "Lord G.," "Renaissance," "Coombe," "Horse Shoe," "Salt Water," "Vyrnwy."

W. H. SIMPSON. (Thanks; we are always glad of suggestions, and will bear yours in mind.)—F. C. D. (Anyone can join, and there are no fees for the club.)—SHRIMPSCUR. (It will be of little use becoming a member if you do not work steadily at the subjects set every month. You alone will be the gainer by such industry.)—PUPIL. (Yes, Mr. W. H. Railton was once a hard-working member of our club, and several others now well known belonged to it in years gone by.)

## Correspondence.

### BOOTLE POLICE-COURTS COMPETITION.

To the Editor of the BUILDING NEWS.

SIR,—On looking through the list of tenders published in your issue of last week, I notice that a contract has been let for the erection of police-courts, &c., at Bootle, for an amount far exceeding the limit named in the conditions issued to competing architects. A clause in said conditions stipulates that "the cost of the buildings including means of heating, ventilating, lighting, boundary walls, railings, areas, pavement of yards, areas, &c., the necessary joiner's fixtures, together with architect's commission, but not including portable furniture, &c., must not exceed the sum of £8,000."

Now, I see by your list that the author of the accepted design gave his estimate as £8,400, and that the lowest of 20 tenders received was £11,678, and this, after some discussion, has been accepted by the town council.

Of course, I do not expect that this decision can now be altered; but I think such unfair pro-

ceedings should not be allowed to pass unnoticed, especially just now, when there is beginning to be manifest a desire to place such competitions on a perfectly fair and equitable basis.

I am of the opinion that in this case many of the competitors would have "thrown a tower in," and made other improvements in their designs, had they have known that an increase on the stipulated cost of 50 per cent. would not be objected to.

Trusting that some explanation will be forthcoming,—I am, &c., H. G.

## CARRIAGEWAY PAVING.

SIR,—It is to be hoped that the City Commissioners of Sewers will not too readily accede to the request of the H.A.P.S. that wood may be substituted for asphalt. I have already ventured the suggestion that the fault lies quite as much, at any rate, with improper shoeing and reverberating wheels; but while horse owners are looking nearer home for one great cause of accidents, it would not be inopportune if paving authorities everywhere cast about for some better substitute for asphalt than wood.

You were so good in a former issue as to insert my proposition for the substitution of sandstone for granite, and my object in the present letter is to cite one instance from past experience of the result of a trial of wood paving in a leading thoroughfare of London in 1840-4, when the traffic was not nearly so heavy as now, and possibly, also, the nerves of residents were not in so shattered a condition.

Is it too much to expect that the present generation will take warning from past mistakes?

Just the same extraordinary advantages had been claimed for wood as now advanced on its behalf, and in 1840 the Marylebone Vestry had 4,000 yards laid in Oxford-street, and its advocates stated: "That it is unnecessary to enlarge upon the precision with which it can be laid down and taken up, the strength of its construction, its extraordinary durability, absence of all noise, freedom of traction, diminution of mud in wet and dust in dry weather, and the increased facility of their removal, its salubrity as regards the health of the public; its superior cheapness over all kinds of roads. The only tangible objection against it is its slipperiness, although it must be self-evident that any kind of road, the nature of which is hard, and where the greasy mud of London is allowed to be brought upon it, must inevitably be attended with this evil; but if the mud be removed the pavement would not be slippery, &c. So much for the flourish of trumpets. Now for the fiasco.

At a meeting of the vestry of St. Marylebone held on the 12th October, 1844, Mr. Scacio (surveyor) reported: "He had minutely examined the 4,000 yards of wood paving laid by the Metropolitan Company between Wells-street and Rathbone-place, and found the surface rough and uneven, with many holes in it. The fir blocks were worn down from 6in to 4½in., and in places to 3in.; while the elm blocks were worn generally from 6in. to 3in. It was difficult to get a whole block out, it was all so worn."

Mr. Harbut said: "The first cost had been £2,100, and it had cost £210 per annum for three years to keep it repaired, equalling £2,710, or 3s. 6d. per yard per annum. If the same space had been paved with granite, it would have cost 600 per cent. less than wood. The repair of 'Macadam' only cost 1s. 11d. per yard, and this rubbish had cost 3s. 6d." The report was adopted, and copy sent to the Metropolitan Company, with notice to put the road in efficient repair forthwith. (Specimens were laid on the table.)

Comment is surely needless, and yet there is wood in possession again in 1890!

Need we turn to the City for corroboration of this West-end experience? One instance will suffice.

In September, 1846, the City Sewers resolved "That the wood paving in Cheapside do remain till next spring, and then taken up and replaced with granite in the same manner as Fleet-street."

Now that granite has been replaced in its turn by asphalt, what will they substitute for the latter to suit Col. Colville's lumbering cars? I fancy it is pretty safe to predict that it will not be wood.—I am, &c.,

Hampstead, Jan. 14.

E. W. HUDSON.

P.S.—May I offer a remark or two on the recent letters to the Times? Sir R. Rawlinson reminds us that the concrete bed is the actual road; but surely he does not mean us to info-

hat the best cement-concrete base will ever make pine, or any wood, wear equally. Will any two adjacent blocks ever wear in the same degree?—one cut near the heart, and another from the outside of the tree; and if all were to be cut from the outside, how long would the wood wear? I leave the salubrity of wood for the aculeity to discuss, but was glad to see Mr. Forbes's letter anent horseshoes and the asphalted oads of Washington, though I believe it is not suitable for our Metropolis; but respecting the modern shoe, he has many naturalists with him. Mr. Muir advocates granite, with the setts placed diagonally. It seems to me of little or no advantage. With well-made "setts" (and they are not generally so), traction would be just as easy with rectangular courses. I venture to doubt if granite can ever be made free from noise, lay it as we may. Why not give sandstone, which is not so sonorous, a trial?—E. W. H.

#### VANDALISM AT DADLINGTON CHURCH, LEICESTERSHIRE.

Sir,—Archæologists, and everyone who takes pride and delight in our village churches, will earn, with mingled feelings of disgust, shame, and regret, that this quaint, old, square, wood belfry, covered with oak shingle (I believe, unique in Leicestershire), has disappeared, and a fourth-rate fancy-tiled villa turret type of thing put up in its place. The curious old windows, which did duty for a clerestory, have been ruthlessly bricked up with red bricks, and other vagaries are contemplated with the old wood porch, "if the funds hold out." Surely some steps ought to be taken to stay the destroyer's hand. No architect has been called in.

From a personal inspection of this old belfry in August last, I have no hesitation in saying that, at a comparatively small outlay, it would have done duty for centuries.

The chancel was faithfully repaired, and partly rebuilt, two or three years since under Mr. Ewan Christian, architect to the Ecclesiastical Commissioners.—I am, &c.,  
Hinckley, Jan. 21, 1890. H.

#### "HAYWARD (DISTRICT SURVEYOR) v. SANDON."

Sir,—In some remarks as regards this matter which you published on the 10th inst., I wish to point out some misleading statements, which I beg you to correct.

It is stated that "the summons was dismissed"; yet that could scarcely be, as no summons has issued but the one heard on Oct. 4, 1889, when the magistrate decided in favour of the district surveyor, giving him also costs in the case. Also, it is stated that my solicitor gave me certain advice which he actually did not give. Why anyone should write to you, professing to now and publish what passed between "my solicitor" and myself, I am at a loss to conceive; though in justice to Messrs. Sandon's adviser, I am led to believe this statement did not emanate from him.

What actually happened was this:—Messrs. Sandon, being dissatisfied with the magistrate's decision and the order that he made on Oct. 4, that they should pay the district surveyor the pecified fees, endeavoured to get a case stated or the superior Courts. Failing to obtain this in their own way, it was discussed in the magistrate's own private room, and "dismissed," if that is the word, and so the matter remained *in statu quo*.

As I made no demand for costs, of course none were given.

Since then the matter has been settled by Messrs. Sandon paying me what I have chosen to accept in satisfaction of my fees. But be it quite understood that the decision of the Bowditch Court confirming that of all other Courts in favour of the district surveyor's contention is still unshaken, and that Clause 27 of the Act remains to be read as it always has been, and Messrs. Sandon's contention has only confirmed a meaning to be just what it says in its several clauses.—I am, &c.,  
C. H. HAYWARD.  
47, Museum-street, W.C., Jan. 22.

#### ERRATUM—"CARPENTRY AND JOINERY."

Sir,—There was a slight mistake in Fig. 189 of the last article on "Carpentry and Joinery"—viz., the line of the bottom of the sill of the sash should be a continued level across the gutter, instead of following the semicircular line of the gutter, making impossible for the sash to be opened.—I am, &c.,  
THE WRITER OF THE ARTICLE.

## Intercommunication.

### QUESTIONS.

[10212.]—**Speaking Tubes.**—Will some reader kindly tell me how long a speaking-tube may be? How far is one capable of speaking through an inch tube so as to be heard distinctly?—Geo. B.

[10213.]—**Decoration.**—Will some of your readers be good enough to give me the names of some of the best books treating upon "the architectural use of colour in decoration," &c.?—V. C.

### REPLIES.

[10204.]—**Crushing Weight of Stone.**—For the information of "J. H." and "J. W.," we give the following results of tests of three 6in. cubes of Monk's Fark Bath stone conducted by Kirkaldy:—

Test 3361	crushed at	210.9 tons,
" 3382	"	181.0 "
" 3383	"	172.6 "

being an average of 188 tons per square foot.—HAYWARD AND WOOSTER, Walcot-street, Bath.

[10205.]—**Surrey Churches.**—Lingfield Church (dedicated to SS. Peter and Paul) is a large "Perpendicular" building with a fine range of aisle windows. It possesses some good brasses and altar tombs belonging to the Cobham and other families, also some interesting carved "miserere" stalls in the choir. Adjoining the churchyard are some very quaint cottages. There is a fine old house in the village (1617) built of stone, much restored, but worth a visit. It is illustrated in the A. A. Sketchbook. Edenbridge Church (SS. Peter and Paul) has some very good decorated caps to the columns of the nave arcade, and several brasses. Hever Church (St. Peter) contains a fine Perpendicular altar tomb and brass, much decayed, of Sir Thomas Bullen, 1538. A rubbing of the brass may now be seen in the Tudor exhibition in Regent-street. Hever Castle, formerly the residence of the Boleyn family, originally built in the reign of Edward III., is a Tudor house with an interior courtyard, and surrounded by a moat. The long gallery or ball-room has an ornamented stucco ceiling, and the walls are covered with good oak panelling divided by small Ionic capped pilasters. There is also good work to be found at East Grinstead, and Chiddingstone has some most interesting houses in the village.—A. C. W.

[10206.]—**Strains.**—With "Como's" permission, I will answer his question by using the formula for breaking weight given by "Stoney"—viz.,  $BW = \frac{4adS}{l}$ .

Here  $BW$  = breaking weight

$\frac{BW}{6}$  = safe load for timber

$a$  = sectional area of beam

$l$  = depth in inches

$l$  = length

$S$  = constant or modulus of rupture, which for Baltic fir = 12cwts.

Applying "Como's" example—

$$90 = \frac{4 \times 12 \times a \times d}{240} \therefore 90 \times 240 = 48ad \\ \therefore ad = \frac{90 \times 240}{48} = 450 \text{sq.in.}$$

Now let "Como" assume any quantity for  $a$ , say 50, then  $d = 9$ , and the breadth will be  $\frac{50}{9} = 5.5$   $\therefore$  the size of beam required is 9in. by 5.5in.—Geo. B.

[10207.]—**Bridges with Skew Arches.**—Messrs. Crosby Lockwood and Son publish two books on this subject, "Oblique Arches" and "Oblique Bridges," which might assist "J. M. L."—H. L.

[10207.]—**Bridges with Skew Arches.**—Consult or study Buck's "Oblique Bridges," published by Lockwood and Sons, or any elementary work on masonry, such as Dobson's "Masonry and Stone-cutting."—G. H. G.

[10208.]—**Perspective.**—Many books on perspective are published. Chapman's "Introduction to Perspective," or the manual used by the Department of Science and Art may be studied. I should advise "Diligent" to join an art class.—G. H. G.

[10208.]—**Perspective.**—I think Burchett's "Perspective" is one of the best books; there are articles in Cassell's "Technical Educator," also Perspective for Beginners in "Weale's Series." If "Diligent" could get some friend to give him a few lessons, he would learn very quickly.—H. L.

[10210.]—**Ventilation.**—"M." cannot do better than read "Warming and Ventilation," by Sir Douglas Galton in "Our Homes" (Cassell and Co.), and many articles during recent years in the columns of the BUILDING NEWS.—H. L.

[10211.]—**Party-Wall.**—It will be rather difficult to compel B. to remove his pilaster after 25 years, and I suggest a friendly compromise, especially as the frontage is so valuable to A. Is it not possible that the wall originally belonged entirely to B's house, and that A's house was built against it—a very common thing?—H. L.

[10211.]—**Party-Wall.**—A. cannot now compel B. to remove his pilaster if it supports anything; but if it is merely an ornament he may at least represent the facts to B., who would no doubt see the justice of A's requirements. 20 years' enjoyment is necessary to acquire a right to a projection, such as the eaves of a house over the adjoining land, and this term would give B. a right to his pilaster.—G. H. G.

[10211.]—**Party-Wall.**—I do not think that B. can have any claim of right to more than his own moiety of party-wall unless any agreement with regard to the same has been arrived at between existing or previous owners. Failing this, A. should be perfectly justified in removing the encroaching portion of pilaster.—R. WATSON.

## Our Office Table.

THE death is announced of Mr. George F. Durand, vice-president of the Canadian Society of Architects, which occurred at London, Ontario, recently. Mr. Durand was young in the profession, being only 39 years old, but was very widely and favourably known among architects and the public, both in Canada and elsewhere. He was a native of London, Ont., but after spending a short time in the office of the city engineer there, he went to Albany, N.Y., where he was employed by Mr. Thomas Fuller as his chief assistant in the work on the new Capitol, which was then in Mr. Fuller's hands. When Mr. Fuller was superseded, Mr. Durand left Albany with him, and, after a year spent in Maine, with a granite company, he returned to his native city, where he soon found constant and profitable employment, having for several years built a large part of the most important structures in Western Ontario.

THE *Leeds Express* recently attacked the action of the committee of the town council of that borough in ordering the walls of Kirkstall Abbey to be stripped of the covering of ivy. Mr. John Tweedale, F.R.I.B.A., has replied, pointing out that this is an exhibition of misapplied sentiment, for "that rare old plant, the ivy green" has worked its way into the joints of the masonry, opening them out and levering the stones out of position, while stems of the parasite three and four inches in diameter thread their way through the wall, exercising an immense and growing power for evil. Anyone can, as Mr. Tweedale remarks, cultivate ivy on the walls of his own house, and when tired of the cult can cut it down; but Leeds possesses but one Kirkstall Abbey, and the committee would be false to their trust if they did not take steps for its preservation.

AN archæological congress was opened at Moscow on Monday in celebration of the 25th anniversary of the local Archæological Society. In the proceedings, which will be continued until the 5th Feb., delegates from every learned society in Russia and many German and French corresponding members will take part. The Moscow section of the Russian Imperial Historical Museum, which will be maintained under the auspices of the Society, was formally opened on the 8th inst. by the Governor-General, Prince Von Dolgoroukoff. The exhibits include a variety of antiquities from the Caucasus—the spoils of many tombs and tumuli, over 3,000 stone and glass ornaments, enamelled jewelry of the 4th or 5th century, from Kalonga, Merovingian gold ornaments, ancient Icons or holy images, early silver plate, and some antique garments and china.

### MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Royal Academy. "Roman Architecture," No. 1, by Prof. Geo. Aitchison, A.R.A. 8 p.m.

Surveyors' Institution. "Landed Incomes," by H. H. Smith, F.S.I. 8 p.m.  
Society of Arts. "The Electro-Magnet," Cantor Lecture No. 2, by Prof. Silvanus P. Thompson. 8 p.m.

TUESDAY.—St. Paul's Ecclesiastical Society. Annual Dinner. First Avenue Hotel. 7 p.m.  
Society of Architects. "Electricity in the Dwelling," by E. Percival Allam. 7.30 p.m.

Society of Arts. "Relation of the Fine Arts to the Applied Arts," by E. C. Robins, F.S.A. 8 p.m.

Institution of Civil Engineers. Discussion on "Recent Dock Extensions at Liverpool," and paper on "Bars at the Mouths of Tidal Estuaries," by W. H. Wheeler. 8 p.m.

WEDNESDAY.—Society of Arts. "The Utilisation of Blast Furnace Slag," by Gilbert Redgrave. 8 p.m.

THURSDAY.—Royal Academy. "Roman Architecture," No. 2, by Prof. Geo. Aitchison, A.R.A. 8 p.m.

FRIDAY.—Architectural Association. "Free Libraries," by E. W. Mountford. 7.30 p.m.  
Royal Institution. "Smokeless Explosives," by Sir Frederick Abel. 9 p.m.

Architectural Association, 9, Conduit-street, W.—January 31. "Free Libraries," by E. W. Mountford, Esq. 7.30 p.m.

FRED. R. FARROW.  
ERNEST S. GALE. } Hon. Secs.

At the last meeting of the West Hartlepool town council the salary of the borough engineer, Mr. J. W. Brown, A.M.I.C.E., F.G.S., was, by a large majority, increased from £400 to £500 per annum.

## LEGAL INTELLIGENCE.

**THE LONDON SCHOOL BOARD AND ITS CONTRACTORS.**—**JOHNSON V. HELBY AND JOHNSON V. HAZELL, WATSON, AND VINEY.**—These cases were heard on Saturday, Monday, and Tuesday before Mr. Justice Field and a special jury as a consolidated action; the plaintiff, Mr. William Johnson, builder and contractor, Wandsworth Common, suing Mr. Helby, a member of the London School Board, and the printers of the Board, to recover damages in the case of the first defendant for slander, and in the case of the latter for libel. The defendants pleaded privilege and denied malice, and Mr. Helby counter-claimed for libel. In the course of the sittings of a special committee of the board Mr. Helby said the question of "retention money" depended upon the character of the man, and added, "We know that Mr. Johnson is a man without any means at all, and ten years ago he was a carpenter." He further said he took it that the committee would not give a job of £10,000 to a contractor who ten years ago was working at his trade of carpenter with his own hands. The plaintiff, a contractor, who was said to be originally a plasterer and a self-made man, stated that there was no foundation for the statement that he was a man without means. For the defence it was stated that the defendant acted without any malice, and in the interest of the public in the course of his duty as a member of the committee, and that the occasion was privileged. The words of which defendant complained were contained in letters to the chairman and secretary to the board, and imputed to him animus against the plaintiff in consequence of business disagreements. In the end the jury found a verdict for plaintiff, awarding him £200 damages against Mr. Helby, and £2 damages against Messrs. Hazell, Watson, and Viney as the printers.

A new church is being built at Lockerby, Hants. It is Gothic in style, and will be built of stonework, with red brick for internal walls. It will have a tower containing a peal of bells and a spire. Messrs. Goddard and Son, of Farnham, are the builders.

The Purification Commissioners for the Water of Leith, Edinburgh, have approved the working plans and specifications for sewers in the landward district, prepared by Messrs. Leslie and Reid, of Edinburgh.

## Trade News.

## WAGES MOVEMENTS.

**DARTMOUTH.**—The journeymen carpenters and masons of Dartmouth, Devon, held a meeting on the 18th inst., and passed a resolution asking the master builders to give a 10-hour day with 6 hours on Saturday. The master builders on the 22nd replied by having a dinner among themselves, and, it is understood, will grant the men's request. Messrs. Simpson, Strickland, and Co.'s engineering works and manufactory for Kingdom's patent launch engines have opened up trade in this season. The hour system is expected to begin on Feb. 18, if not before.

## CHIPS.

New co-operative stores at the junction of High-street with Roxburgh-street, Galashiels, are now ready for occupation. The block has a frontage to High-street and Roxburgh-street of 181ft., and is four stories high. There is a court in the centre, around which all the shops, back-shops, workshops, and store-rooms are placed. The engine-room is in the south-east corner, and a gas engine of 7H.P. works the hoist and supplies the motive power for driving the baking and other machinery and the ventilating fan. The total cost of site, buildings, and fittings amounts to about £14,000. The architects and builders are Messrs. J. and J. Hall, Galashiels.

The Carmelite Priory at the west end of the town of Queensferry, which for a period of about 250 years has been used only as a burying-place for members of the family of Dundas of Dundas, to whom it belongs, is about to be put in a condition to fit it for a place of worship in connection with the Episcopal Church Mission at South Queensferry. The restoration is to be carried out under the supervision of Mr. Kinross, architect, of George-street, Edinburgh.

The Centenary Wesleyan Chapel in Trelowarren-street, Camborne, was reopened last week after renovation and improvement, effected at a cost of £1,100. Mr. Oliver Caldwell, of Penzance, was the architect, and Mr. James Rouse, of Camborne, was the builder.

The Richmond Select Vestry have unanimously approved the introduction of a Bill into Parliament for the construction of a lock and foot-bridge on the Thames in the neighbourhood. This decision will have to be confirmed by the ratepayers in public meeting assembled before any final action is taken.

On the 21st inst. the foundation-stone of the new Masonic hall in course of erection in Duncombe-street, Kingsbridge, for the Duncombe Lodge, No. 1486, was laid by the W.M. Bro. H. D. Adkins. The builder is Bro. Geo. Hooper, of Kingsbridge; the plans having been prepared by Bro. R. Watson, in the office of Mr. W. M. Tolit, architect, of Totnes and Kingsbridge.

On the 8th inst. the Main Roads and Bridge Committee of the Glamorganshire County Council met to interview the following ten gentlemen for the appointment of county surveyor:—G. B. Carlton, Beckenham; W. Santo Crimp, Wimbledon; J. Dormer, Armagh; T. Lloyd Edwards, Aberdare; F. J. Harvey, Merthyr Tydvil; S. A. Hutchins, Cardiganshire; J. Parker, Hereford; John Price, Toxteth Park; R. J. Thomas, Carnarvonshire; and G. Watheys, Llanelly. The committee reduced the number to five, as follows:—John Price, F. J. Harvey, S. A. Hutchins, T. Lloyd Edwards, and R. J. Thomas. These gentlemen attended upon the County Council on the 16th inst., with the result that Mr. T. Lloyd Edwards, of Aberdare, a local candidate, was elected. There were 104 candidates for the office, the salary offered being £600 a year, with an additional allowance of £150 towards travelling expenses, &c.

The bronze bas-relief panel memorial of the late Mr. R. Peacock, M.P., is now completed. The panel will be placed in the outer wall of the organ loft at the Brookfield Unitarian Church, Hyde-road, Gorton, which was erected at a cost of £12,000 by Mr. Peacock. The designer of the panel is Mr. J. Cassidy, of Barton Arcade, and the Coalbrookdale Company have made the castings.

At a general assembly of Royal Academicians and Associates, held on Tuesday evening, Mr. Ernest Albert Waterlow, painter, was elected an Associate.

Mr. John James Downes, of 11, The Parade, Lewisham High-road, architect and surveyor, has been appointed to the management of Mrs. Wilson's estate at Eltham.

## HAWKSLEY'S PATENT TREADS.

Proprietor & Manufacturer: J. WESTWOOD, Jun.

NAPIER YARD, MILLWALL, E.

Telegraphic Address—"Westwood," London. Telephone No. 5065.

Recommended for durability, simplicity, firm footing, elasticity, and are perfectly noiseless; they excel lead, oak, teak, or stone; applicable to wood and iron staircases, new and worn-down stone stairs, spiral and other staircases, footpath flaps to cellars, covers for drains and coal-cellars, flooring for public buildings and aisles of churches, &c., &c.—The best and most durable Tread or Step yet invented.

FRIDAY, JANUARY 31, 1890.

### PARTY-WALLS AND ADJOINING OWNERS.

THE rights and obligations of those who are joint-owners of party-walls are so explicitly stated in the Metropolitan Building Acts that one would scarcely imagine how differences are likely to occur, were we not to bear in mind the number of building operations going on in London, together with the complex and nice questions that are brought up for magisterial decision. A building owner takes down his premises between two other houses, and in so doing disturbs seriously the wall on one side or the other. He has a right to pull down and rebuild it if it is so far defective as to make it desirable, with the consent of the adjoining owners; but in many cases this consent is withheld, or the structure is pronounced dangerous, and provisions of the Dangerous Structures clauses apply. In either case the adjoining owner suffers inconvenience or damage, and there can be no wonder that a disagreement should arise. It often happens that the building owner, in taking down any portion of the party structure, such as jambs, causes cracks or settlements to arise in the adjoining premises, or the foundations may be undermined by excavation, and the owner of these premises naturally looks to the builder for recompense. A constant source of litigation can be readily apprehended in this way, notwithstanding a learned lawyer (Mr. Justice Kay) declared the other day in a case brought before him ("Charles v. Gover") that London architects and contractors went to work as if there were no such Act as the Metropolitan Building Act in existence, and they did not take the slightest pains to act in accordance with it. In the case to which these remarks were applied an owner utilised a defective party-wall which had been condemned under the Dangerous Structures clauses. The charge upon architects and builders is uncalled for when we consider the nature and complication of the cases likely to arise. That a great many rotten party-walls are built upon or utilised there can be little doubt. The statutory rights of adjoining owners are not always exercised or enforced, and the utmost vigilance of the district surveyor is necessary in order to make sure that a defective wall is not built on to or raised. The sound half of the wall often has to bear all the weight and strain of the increased height. Chimney jambs and breasts are often pulled down on one side, which considerably weakens the structure attached to them, and no substitution is made. The foundations are frequently tampered with. Adjoining owners are often remiss, and if the district surveyor is not watchful, much damage may be done to their property.

One of the dangers to which the adjoining owner is exposed is the right given to the builder of "cutting away any footing, or any chimney breasts, jambs, or flues projecting from any party-wall in order to erect an external wall, or for any other purpose." Though the condition immediately follows of "making good," it is not so fully complied with. The act of cutting away and breaking the bond shakes the work of the party-wall, and if the wall has partly received its support from the footings and jambs, their removal is a serious disturbance. The Act does not give the adjoining owner the means of ascertaining the actual nature of the case; his only security is to employ a surveyor to

see that his neighbour really carries out the intention of the law. We have known a party-wall practically destroyed as a solid homogeneous structure of division by holes and chases cut into it for beams and partitions—a right which the builder can exercise under the 82nd section.

The complacent neighbour, assuming that the builder will do all right, does not interfere, but afterwards discovers that his walls are much shaken and cracked, and that the end of a timber beam has been thrust through, regardless of the proximity of a flue. At the moment these cuttings were made and the work concealed, the surveyor was not present. Not infrequently, a party-wall is found to have considerably overhung the neighbour's ground, owing, perhaps, to excavations in the basement, and the Building Act allows the building owner to "cut away or take down" such parts as overhang in order to erect an upright wall. Here also the neighbour may suffer damage through no fault of his own, as in nine cases out of ten the wall has declined owing to improper underpinning or excavation on the other side, and the right of support has been acquired by lapse of time.

Other questions regarding party-walls in respect of ownership are frequently perplexing. The wall may belong entirely to one of the two owners of adjoining land subject to an easement of uses belonging to the other owner; it may have been erected on land belonging to both owners in equal moieties as tenants in common; or the wall may be erected in two halves divided longitudinally, in which case one owner has a right to cut down the half on his own land. In the first case it is evidently unjust that the owner of wall should be subjected to the inconveniences of a building owner who wishes to cut down his half of the wall, or of correcting the verticality of the wall; in the second instance there is a legal right of partition, the owners are tenants in common, and this applies to the greater number of party-walls. Each owner has his remedy against the other for any injury done to his portion. In the third case cited above, where there is a longitudinal division, each party can pull down the portion of the wall standing on his own ground, unless there are circumstances from which a grant of an easement conferring a right of support can be implied.

These legal dicta are necessary to be borne in mind when one owner, in making alterations, finds it necessary to interfere with his neighbour's portion. When one portion of a party-wall cannot stand without the support of the other half, as in the case of a wall overhanging, there is certainly a difficulty in deciding what course ought to be pursued. If both premises at one time have been in the hands of the same owner, a strong presumption may be held that a right of support was conferred on the adjoining neighbour. A question of some doubt arises in a case such as that stated by a correspondent in our Intercommunication Column. A. desires to rebuild his premises; but it is found that the adjoining owner, B., has a pilaster which encroaches on A.'s moiety of the party-wall to the extent of some inches. Can A. compel B. to remove his pilaster, which has been in existence over twenty years? Here we have a common incident. B. probably has a right to the party-wall which may have been built on his own land, and A.'s house may have been built against it. If so, of course A. cannot compel B. to remove the pilaster. If the wall belongs to both owners as tenants in common, B. has still an easement which cannot be easily set aside; an original owner of B.'s house may have also been owner of A.'s house, in which case a right of support was conferred on the neighbour, or both owners may have come to an agreement. Let us take another instance: A building owner pulls down his house, and in doing so

has been obliged to take down a chimney belonging to his neighbour, and which received support from it. The wall is only half a brick thick, and is exposed to the weather, and below piers and arches carry the upper portion, making recesses in the building owner's house. Is the building owner liable to rebuild his neighbour's wall and make good the damage? Certainly, as a building owner cannot remove a wall that has been used as a party-wall for so many years without injuring his neighbour, and he is certainly liable for the support of the chimney as a party structure. The owner of the adjoining premises having acquired a right of support is entitled to a restitution. A similar principle of law or common fairness can be applied to other circumstances in which acquired rights are at stake; but in many of these professional advice and friendly negotiations between the parties may do more than litigation.

### CO-OPERATION OF THE PROFESSION AND TRADES.

WE have always thought that if a meeting-ground could be established between architects, artificers, and craftsmen connected with building, great facilities would be offered to each class, and many of the obstacles removed which now interpose in the carrying out of designs. Let us take for example the requirements of an architect. He is engaged to design and prepare contract plans for, say, a theatre, in which it is desirable that the most approved appliances should be introduced in the way of stage construction and fittings, electric-lighting, ventilation, fire-resisting construction, unflammable materials, and decorations. His experience may have been hardly sufficient to acquaint him with these points, or, what is more probable, he may be perfectly ignorant of new methods and inventions. An hour's intercourse with an expert in these questions, or an inspection of an exhibition of specialties, would enable him to sit down and complete his drawings and specifications with composure; it would supply him with the practical information he wanted, and which no treatise or guide could give him. An interchange of views of this kind is what the young professional architect is most in need of. None of the architectural societies have as yet furnished their members with a meeting ground of this description, a sort of exchange in which the views of professional and practical men can be discussed for their mutual advantage. Reading papers and discussing them are valuable means of imparting and acquiring knowledge; but they do not supply the wants of a man who requires to know something definite, to discover someone who would undertake any special work, or to see something that will suit his ideas, and that he can specify. A library of reference books is valuable, but, as a practical correspondent said the other day, the hunting up of any question is too laborious, and, as we all know, many of the details we require are not treated in books: they are matters which the authors appear to think beneath their notice; in other instances, owing to the ever-increasing number of "book-makers" and compilers, the subjects are treated too superficially to be of any value to the architect.

The idea of an exchange is not new; we have plenty of exchanges, from Stock Exchange to mercantile exchanges. In America and Australia the idea of a builders' exchange has taken a firm hold on the trade, as those at Sydney and Melbourne; at the latter city several meetings have been held for the purpose of establishing such an exchange. The object is to enable the builder to find what he wants; if he wants to see in the course of the day a blacksmith or a bell-hanger, he can do so by calling at the exchange. What the Sydney and Melbourne

builders are doing might be done in London and other large centres if only the architectural societies helped the movement. It would be desirable for architects, builders, manufacturers, and artisans' craftsmen of various industries to join in the establishment of an exchange of this description. The manufacturer, the patentee of new appliances and materials, the craftsman and the artist would become members, for each would be directly benefited. To sketch out a scheme for an exchange of this sort is not our intention here, but simply to indicate what benefits are likely to accrue to professional men, builders, and tradesmen.

One of the obvious disadvantages under which the architect works is his inability to obtain information on the shortest notice. He wants to know when preparing his plans or writing his specification the space or area occupied by dual desks in a schoolroom, or the length and width of a seat in the plan of a church or a theatre. To turn to published rules or to precedents would cost him, perhaps, a fruitless search of probably several hours. There are makers who could give him the exact dimensions at a moment's notice or models to which he might refer if he knew where to go to find them. How many architects wish to know how to build cavity walls and to specify the right number of cramps for a given area of wall; the number and distribution of flues for warm air; the kind of heating apparatus that should be specified, and what provisions should be made? Numerous queries arise in designing the details of terracotta, and of cast or wrought-iron, matters which are inadequately provided for and specified simply because the architect cannot refer to working drawings or books dealing with them, and is consequently obliged to describe them in a very general manner or leave them to the manufacturer or engineer. Special fittings for technical schools, laboratories, and museums are amongst the many things that ought to be known before proper detail drawings can be given. When we come to the purely technical requirements of building, the architect is in greater need of aid: he is obliged to have recourse to the trade circulars and descriptions of engineers, and is often compelled to specify apparatus and fittings without knowing which are the best for his purpose. A museum of appliances would enable him to see at once which of the several principles was most suited to his wants: he could there obtain their cost, and would be able to specify the particular form of apparatus with precision.

Hydraulic lifts, heating apparatus, electric lighting are three of the requirements of modern buildings; but the architect knows practically very little about either of them. There is no treatise published which gives him any rules or data to work upon, and even if such could be obtained, the practical experience of the manufacturer becomes indispensable. In making provision for a lift, it is essential that the architect should be placed in communication with the engineer before the former can complete his plans as to the necessary excavation or boring for cylinder, size of lift, &c. If he could be informed of the kind of lift and the conditions of successful working, it would be of much service to him. He ought to know something of the systems used and the requirements if he desires to avoid the mistakes that others have fallen into by not acquiring rudimentary facts in connection with the subject they are dealing with. To illustrate our meaning, the architect is often called upon by a client to advise him as to the fitting-up of a lift, and the power required. The adviser, knowing little of hydraulics or the laws of transmitted power, makes the mistake of thinking the power of the piston in the cylinder multiplied, whereas in point of fact, no more foot-pounds of

energy are given out than are supplied to the piston or ram, or 2,240ft.-lb. on the pump-plunger will only give 1ft.-ton on the piston. What is gained in power is lost in velocity. To take another question—that of electric lighting—some knowledge on the part of the architect is looked for. He cannot possibly advise, much less specify, till he knows the requirements, the probable cost, and details of lighting arc or incandescent lamps; the difference between connecting on the two systems, the number of "switches," the motor, dynamo, or batteries; the mode of connection, such as the "connecting in multiple" or "multiple series." These and other technical points of an electric-lighting installation must be learned, and no one but an electric engineer or a manufacturer can supply the necessary information. The electromotive force in "volts" or the quantity of "ampères" to give a certain candle-power light must be known before any idea of cost can be obtained. As to fittings, such as brackets, electroliers, and other appliances for lighting, recourse must be had to a well-stocked museum or showroom. The same want of information is found in various other trades; the architect, even if he provides for a separate contract, must have some particulars, he requires to know how the particular thing, say that of electric lighting, or revolving shutters, or lifts, or fireproof flooring, is usually managed or fitted. If he is for the first time planning a board schoolroom, a hospital ward, a laboratory, a brewery, or billiard-room, or even such ordinary buildings as a conservatory, a stable, a racket court, he requires to know the most desirable plan or proportions to follow, what rules of lighting and ventilation are to be observed, what fittings are necessary. Books will not help him, he must either see other buildings or good models, or must obtain particulars from someone versed in the construction of any of these structures. How many are the applicants for specific information of this sort may be seen by looking through the columns of our "Intercommunication." How to lay a spring ballroom floor, how to construct and heat a swimming-bath, how to build an oven, how to ventilate a room, how to improve its acoustics, how to plan a cabmen's shelter, are but a sample of questions put on specific subjects. Information must be gleaned from inspection, or application to those who have it to give. In these ways the exchange may be rendered helpful to the architect; but there would be a reciprocal benefit conferred. We have often noticed the evidences of a want of sympathy. The work of the manufacturer and tradesman may be excellent as a specimen of executive skill and workmanship, but not pleasing to the architect's mind. In exchanging their opinions and remarks, both would be deriving a benefit—the architect would be learning the technical requirements, the tradesman or craftsman the views of one who regarded the work from an art point of view. Better manufacture, improved workmanship, more tasteful productions would be the result of an interchange of thought between the manufacturer and the architect. For want of this co-operation we have to pay heavily for designs of a special class. Manufacturing firms can dictate the details of buildings, and are in a position, owing to their technical knowledge, to prevent or hinder any improvement that may be suggested. So long as designing of buildings is in the hands of professional men who will not study workshop methods and details, and the design and workmanship of fittings and details are in the hands of the manufacturer, there will be disunion and a working apart of the two classes. Castings of constructive and ornamental ironwork will continue in the market that cannot be justified from an architectural point of view; ready-made mouldings will offend against

correct taste, plaster castings, manufactured decoration, wrought-iron fittings and brass-work will be thrust upon architects and employers who are unable or unwilling to require anything more in accordance with the requirements.

Co-operation is desirable in other ways. There are numerous architects who would like to engage artists and craftsmen of repute; but who have no other means of doing so than through the contractor. Let us suppose an architect engaged in carrying out a design in which iron entered. He would not care probably to go to an engineer who was a specialist to prepare designs and give an estimate; but if he could consult anyone who had experience in executing such work it would be of service. He could depend on the details being carried out skilfully. Or in a scheme of decoration, an architect prefers to put the design in the hands of decorators of repute, men whose skill and artistic judgment can be fully depended on, who would carry out the details of ornamentation from his sketches, and prepare cartoons or models for inspection. For example, the decoration of a church, or the auditorium of a theatre, requires the engagement of artists who are ready to devote their time to the preparation of studies, and are able to suggest a scheme of colouring. The failure of these designs is partly due to the habit of leaving it to a contractor who employs his own men or sub-lets the works to others at a price which cannot insure success. To establish a relation between architects and art craftsmen, is one of the reforms we want, to place art in the position it once occupied; it is of little use to expect co-operation to follow from technical instruction and patronage of arts and crafts exhibitions—personal intercourse between the designer and the workman, between manufacturer and artist, employer and employed, is the only way of creating an understanding and of awakening a sympathy between them.

#### A GALLERY OF ARCHITECTURAL WATER COLOURS.

THIS week an exhibition has been opened in the galleries of Mr. McLean, in the Haymarket, of water-colour drawings, by Mr. Edward H. Bearn, illustrating German and Italian cathedral towns, and their picturesque streets and architecture. All those who have an eye to colour and enjoy its free use, coupled with an unrestricted artistic fancy, will appreciate the collection thus industriously brought together, and if there is one thing to be noticed, perhaps, more than another, it is the lively aptitude of this painter for his work (of which he seldom seems to tire). We cannot always feel that truth to nature is a primary consideration with him; he is clearly far from being a master of technique, and sometimes his imagination results in making the buildings he paints resemble stage-play architecture—judged, that is, from an architect's point of view. We greatly prefer his quieter studies, and No. 1, from Pistoja, if one of the least, is one of the most successful bits in the gallery. The Venetian Boats (No. 8) are boldly done in brilliant colours, and act as a clever foil to Sta. Maria della Salute, shown in the middle distance. Not that Mr. Bearn avoids drawing monumental architecture to a good large scale, for this same beautiful church is worthily painted in No. 26, a lovely study in yellows and blue, or in No. 19, where again this identical building in a Turner-like view illustrates the lines:

"Column, tower, and dome and spire  
Shine like obelisks of fire."

Amalfi Cathedral, with the great range of steps rising in front of the western portals, is another picture which pleases us, and the Campanile of the Palazzo Pubblico at Siena

crowns a good study of Italian street life with some characteristic and well-drawn oxen in the foreground. The melting tones embodied in the "Fruit Stall, Castellamare" (No. 21) are exquisite in point of colour, but any mere realism is clearly not intended. The Market-place at Ratisbon at once furnishes a very grand subject, with the great cathedral spires coming with lordly grace in the middle picture, and the familiar fountain in the centre of this busy scene. The Grosse Ring Platz, Prague, and another on the Old Bridge, in the same place, are to be reckoned among the best, brightest, as well as most soft and true, of this painter's productions here shown. The after-glow on the Lagoons of Venice is also full of tone, and gives an exquisite sunset effect, and the same may be said of his view overlooking the river at Rome, with St. Peter's, the Fortress, and the Bridge, for, although the subject has been done to death before, so to speak, this study gives so refined a touch to nature as to render the painter's picture even fresh, and certainly welcome. Another exhibit of the same order of merit may here, too, be noted—viz., No. 54, under the lines:

"And the crimson pall of eve may fall  
From the depth of heaven above."

Heidelberg Castle, the Spanish House, Ghent, the showy drawing of Augsburg Cathedral, Views in Nuremberg, and others in Venice, serve to give variety and illustrate the painter's love of his work. The exhibition to the architect certainly is worthy of a visit.

#### MISSION HALL, GOSWELL-ROAD.

THE illustration shows the elevation of this hall, which it is proposed to erect for the mission work in connection with St. Paul's, Clerkenwell. The elevation is to be executed in red brick with terracotta dressings, the internal construction to be of fireproof material for floors and staircases. In the basement will be lavatories and stores, and a large kitchen for preparing teas, &c. The architect is Mr. Henry Ough, of 16, Austin Friars, E.C., and the lowest tender in a limited competition was that of Messrs. Wall Bros., of Kentish Town.

#### ROMAN ARCHITECTURE.\*

THE magnificent public buildings of Ancient Rome attracted the attention and excited the admiration of mankind from the time of their erection. Nearly all the Roman writers have mentioned them with affection or pride, from Plautus (254 to 184 B.C.) to Ammianus Marcellinus (370 to 390 A.D.), who was the best of the Roman writers, and he tells us of the admiration excited in Constantine the Great by the sight of the following buildings in Rome: The Temple of the Tarpeian Jove, the Baths big as provinces, the mass of the Colosseum, the shape and doming of the Pantheon, the Temple of the City, the Forum of Peace, the Theatre of Pompey, the Odeum, and the Stadium, and the astonishment he showed at the sight of Trajan's Forum. On the irruption of the barbarians, most, if not all, of the public buildings were plundered and partly destroyed. The Popes were, however, enabled to save some by consecrating them as churches, for the barbarians seemed to have had some respect for places of worship in use, though the Scythians burnt the Temple of Diana at Ephesus in the 3rd century (A.D. 260). The Pantheon was dedicated to the Virgin and Martyrs in the early part of the 7th century by Boniface IV. (608-615), and it has thus been preserved to the present day. The Gothic King, Theodoric, as early as the 5th century (455-526), repaired some of the buildings that had fallen into decay—notably the Baths; but the successive irruption of hordes of savages, whose whole delight was slaughter and destruction, converted whole tracts of the Roman territory into wildernesses, thus almost annihilating industry and commerce, and so cutting off the resources by which the public buildings were supported

and repaired. The change, too, of faith, of circumstances, of habits, and modes of thought, caused the abandonment of many of them, and those so abandoned were used as quarries; the burnt bricks and the stonework, the columns, and the costly marbles were used in the construction or in the adornment of new buildings. The absence of commerce made the very iron cramps so valuable that it was found worth while to cut through solid stonework to obtain them; but what was even more destructive was the conversion of the stone and marble into lime,\* which is generally wanted where human life exists. We know that the Mausoleum was made into lime by the Knights of Rhodes, even so late as the 15th century. Roman architecture has claims upon our attention, not only for its intrinsic merits, but as a continuation of Greek

architecture, though with the addition of the arch, the vault, and the dome, and was in fact mainly designed by Greek architects, who were slaves or freedmen; but it has an even greater interest as being the mother of the Byzantine, the Romanesque, the Saracenic, and we may almost say of the Gothic. The grand ruins themselves attracted attention as soon as the barbarians had settled down to peaceful avocations. Scholars, too, sought to identify the ruins of the ancient buildings with those described by the Latin authors. Taste and patriotism both combined to make men antiquarians; they grieved over the daily destruction of beautiful things, and they saw that each beautiful thing destroyed, each column burnt into lime, each building ruined for its brick facing, was lessening the evidence of Rome's former greatness. Cola di Rienzi, the Tribune of the people (1313-1354), was one of the most prominent of the early antiquaries. As soon as the new buildings of grandeur and importance were required amongst the settled towns of Italy

\* A Lecture delivered by Professor GEORGE AITCHISON, A.R.A., B.A., and V.P.R.I.B.A., before the students of the Royal Academy, January 27th, 1890, being the first of a course of six addresses on the subject.

\* Pirro Ligorio says that some large marble cornices and an infinite number of statues found in the Temple of Faustina were broken up and burnt into lime. Prof. Middleton "MSS. notes by Pirro Ligorio," Society of Antiquaries, 1889.

architects were attracted to the Roman ruins, and endeavoured to extort from them their secrets. All architects have read in Vasari of the time spent by Brunelleschi in measuring and studying the Roman ruins, when he was solving the problem of how to dome the Cathedral of Florence, and Donatello was his companion in these studies. Brunelleschi was born in 1377, and died in 1444; in 1453 Constantinople fell, and a fresh impetus was given to the Renaissance by the influx of books, MSS., and works of art, as well as by the scholars, artists, and skilled workmen who had escaped from it. In the high tide of the Renaissance architects flocked to Rome from every part of the Christian world, to measure and study the remains of Roman architecture, while a new light was thrown on the remains by the treatise of Vitruvius, as new lights were thrown on Vitruvius by their study. Vitruvius' book probably held its place as the teacher of architecture throughout the Middle Ages. Galiani, in the preface to his Vitruvius of 1758, tells us from Panormita that Alfonso the Magnanimous, King of Arragon, wishing to restore the new Castle of Naples, had no recourse to others, but to Vitruvius, and because Panormita gave him his Vitruvius, which was without ornament or boards, the king reprehended him, saying that so important a book did not deserve to remain uncovered itself, from which we learn so well how to cover ourselves,\* and at once ordered him to have it nicely bound. Professor Cockerell, in his pamphlet "On the Architectural Works of William of Wykeham" (8vo, London, 1846, page 33), erroneously supposes that it was Alfonso III. (whom he calls the Philosopher), who lived about 1284. It was Alfonso V., who reigned from 1416 to 1458, and whose sayings Beccadelli (called Panormita, from his being born at Palermo) recorded, and which were published in 1485. In this same note Professor Cockerell says: "The evidences of the estimation in which Vitruvius was held in the Middle Ages abound. The citation of his name in the earliest and most authentic documents of the Freemasons is seldom wanting. The church in the Castle of Nuremberg, built by Barbarossa in 1158, and the Fraunkirk, in the centre of that great city, probably of later date, are exact illustrations of the 'Temple in Antis' of Vitruvius, as given by Caesariano (Lib. iii., fol. 52). . . . In fact, it appears that in the Middle Ages, scarcely less than now, it was the intention and aim of the architects on all occasions to establish their rules upon Vitruvian authority; and the illustrations given in the plates of Caesariano may be adduced as sufficient evidence of this traditional respect for the father of architectural legislation." Vitruvius' book was first printed in Rome c. 1486, edited by Sulpicius, and was re-edited and illustrated with woodcuts by Fra Giocondo in 1511, who tells us in one of his books that he shed tears over the destruction of the buildings and works of ancient art that took place in his day. Amongst the Italian architects we have a succession of those who published drawings of some of the ruins of Roman buildings; L. B. Alberti, Sebastian Serlio, who is supposed to have published in his book the drawings of Baldassare Peruzzi, Palladio, Antonio Labacco, Vignola, V. Scamozzi, and others, up to the present century, in which Canina published his "Edifices of Ancient Rome," in six volumes (1848-56), and doubtless there is a vast mass of unpublished drawings. Thirty folio vols. of Pirro Ligorio's "L'Antichita di Roma" are amongst the Royal Archives at Turin. In the 17th century France took up the task, and we have the "Edifices of Ancient Rome" by A. Desgodetz (1682). England at last followed, and Taylor and Cressy's book on the architectural antiquities of Rome was published in 1821-1822. I have not mentioned the monographs on Roman buildings, which are numberless. We all know that every book on architecture, and most of those on any of the building trades up to the middle of the last century, had illustrations of the Roman orders, or of the paraphrases of them by the eminent Italian architects, and many books on architecture, even to this day, contain

them. Looking at the affluence of information we possess on the architecture of the public buildings of Rome, it seemed to me to be more useful to speak of the private houses. Under the head of private houses I include those in town and country as well as those in the capital. I shall try and touch on some of the palaces, as they are but glorified houses. Roughly speaking, the Roman house must necessarily have been the model from which most of the houses of the Western world have been derived, not to speak of the cloisters of cathedrals and abbey churches which, with their gardens, are supposed to have been copied from the atrium of the Roman house. In England the Roman villa was different to that in Italy; the atrium became the forecourt, the rooms at the end and part of the two sides sometimes having a verandah next the court, the open space was the compluvium or impluvium on an extended scale; but in Spain the general arrangement of the Roman house is still adhered to. It is interesting to know something of the type from which most subsequent civilised house-building took its rise, more especially when that wonderful people, the Romans, had, within a short time after its death struggle with Carthage, virtually conquered the whole of those countries which surround the Mediterranean, and had thus become acquainted with the houses and palaces of Greece, Illyria, Epirus, Macedonia, Thrace, Asia Minor, Syria, Palestine, Egypt, and Numidia. The Romans were of all people the readiest to adopt all they considered excellent, and we cannot suppose that they did not seize on each particular form or arrangement that recommended itself to them in the houses and palaces of those countries. We know from Plutarch that Pompey copied his theatre from the one at Mitylene in the Island of Lesbos. In reading the descriptions of the villas of Cicero, of Trimalchio, and of Pliny the Younger, we see the care that was taken to secure proper aspects and delightful views, silence in bedrooms, quietness, and pleasant prospects in studies, and to provide libraries, picture galleries, baths, and tennis courts. We learn how the houses were kept warm. If we were without any express statements of their being warmed, we could see the provisions for warming them in the ruins of the Roman villas in our own country. We have again the precise instructions of Vitruvius for proportioning the separate parts of houses. This subject is greatly neglected in the present day, although it is vitally important if we wish to make our rooms captivate the eye. I recollect hearing Professor Cockerell praise the library of University College, London, which Professor Donaldson had just built, and say it was elegantly proportioned, and showed the ripe study that had been bestowed on it. He added that young men were often excellent in ornament, but rarely attained excellence in proportion, as they had not as yet been duly impressed by its importance. We in England, too, greatly neglect that training which is got by the restoration on paper of ancient buildings. Although the younger Pliny's descriptions of his villas are said to be the most favourite exercises for architects, I only recollect a single published restoration by an Englishman, that by R. Castell in his "Villas of the Ancients." For though the Roman house in the learned Newton's Vitruvius has evidently been inspired by Pliny's Laurentine villa, it is not a restoration of it. The restoration of one or both of these villas has exercised the ingenuity, and displayed the knowledge of Italians and Frenchmen. Why were the Italians of the Renaissance the best architects, and why are the French now? Mainly because the former were and the latter are better trained than the architects of the rest of the Christian world. Let us take an analogous case, the invincibility of the Roman legions. We are apt to take for granted that the Roman legions were invincible, because the Romans were a fighting, determined, and well-disciplined people; but Polybius, who was a Greek and a hostage, and had, therefore, no particular reason to love the Romans, explains to us that the Roman legions were largely composed of other nationalities, and that their invincibility arose from the discipline, and not from the men; and that great master of the art of war, Marshal Saxe, makes a similar remark about the men of his day. We are too apt to omit the complete training obtained by the restoration of ancient buildings, until the problems of actual practice come before us, so that we only get perfectly trained after being engaged in a large practice, whereas we ought

to come to our first building in a well-trained state. We saw in the Paris Exhibition of last year a series of magnificent restorations of Greek and Roman buildings—the Acropolis of Athens, the Parthenon, the Theseum, the Temple of Demeter at Eleusis, the Temple at Olympia, the Palace of the Caesars at Rome, Diocletian's Baths, a portion of Hadrian's Villa at Tivoli, the Pantheon, the Temple of Concord, and the Arch of Titus. Many of the sets comprise the plans and elevations of the ruins as they now exist, as well as the restorations, and some of the drawings must be at least 15ft. long, with every detail of the construction drawn, and the colour decorations restored, and this not by very young students, but by men who would here be in practice. M. Paulin's restoration of Diocletian's Baths is admirable, and has an artistic grace that was probably wanting in the original, while some of the mosaic has that dignity of colour that befits a grand public building; this is especially notable in that with the white ground. This practice of restoration has often been as much objected to by the French public as it has been neglected here; but what does M. Chas. Garnier reply to the objectors who say "What is the use of it?" "Why, unjust and churlish souls, it is useful for the history and palpitating life of the arts; it serves to compare the past with the present, and it serves above all (for that is its end) the artist who has worked! Do you think the time he has passed in measuring those fragments, in interrogating those ruins, in assigning them their place and their employment—do you believe that this time has been lost to the artist? He has familiarised himself with the first notions of art and construction; he has lived the life of other times; he has brought together the history of men and of stones; he has learned to study, to compare, to reason, which he must do later when he builds for you; he has, in short, the alphabet of architecture. Whatever may be his ideas in the future, he will know how to express them. If his colleagues have already done similar work, is that a reason why he should not do them? If my neighbour at college has translated Virgil or Cicero, is that a reason why I should not in my turn? Does the education of one man give education to another. Do not laugh at these ignorant attacks? It is noble self-denial to study one's art in youth in the hope of becoming later a master in one's turn."\* To plan well is an important part of the architect's duties, though not the most important, and it means grouping rooms of the requisite size and shape in a convenient manner and with the least loss of space. The Roman architects were excellent planners, and we learn something of this by restoration; besides, the exercise of adapting plans to other requirements than those of the present day gives additional breadth to the architect's mind; and we have, too, in some Roman buildings vast rooms that are unusual in England. Hitherto I have been speaking about fulfilling the programme in planning; but there is another object we have to attain in important buildings—for want of a better word I may call it noble planning—when the rooms have to be elegantly or majestically proportioned, to be diversified in shape and size, and so contrasted as to set one another off to the best advantage. This sort of planning is mostly required in buildings of State, where beauty, dignity, and magnificence are chiefly aimed at; and what applies to planning is equally true of other parts of the tremendous and complex profession that we follow. We must have deeply studied noble planning, as well as that which is merely suitable, if we are to be successful in making noble plans; so must we study dignified proportion, and exercise ourselves in producing it on paper, if we want our buildings or our rooms to be dignified. No one was a more diligent student of the antique, nor restored more ancient buildings, than Palladio, and he was one of the few who succeeded in attaining the dignity and fine proportions of Roman architecture. To compose well presupposes a study of the art of composition, practice in that art, as well as natural genius; and the same study and the same genius are required for all the different æsthetic branches of our art. Nothing can be a better study for grace and refinement than Greek mouldings, only they are not suited to our climate. We in England, therefore, also want to study Gothic mouldings for their effects of light and shade,

\* Cum incivem illam arcem Neapolitanam instaurare instituit, Vitruvii librum qui de Architectura inscribitur, affert ad se jussit. Allatus est, quando quidem impromptu erat Vitruvius meus ille quidem, sine ornatu aliquo, sine Assensibus: quem rex simul atque inspexit, non deesse hunc potissimum librum qui nos quomodo contemur, tam belle doceat, defectum incedere, eumque mihi perquam politè ac subito cooperiri mandavit. (Lib. I, par. 44, Antonii Panormite, dictis et factis Alphonsi regis Aragonum).

\* M. C. Garnier, "A Travers les Arts," 8vo. Paris, 1869.

so that our mouldings may have the grace and refinement of the former, and the effects of light and shade that are obtained by the latter. I have always been struck in London by the variety and originality of the buildings; but in too many instances the architecture lacks knowledge, taste, and care. In the introductory lecture of a course, some digression may, I think, be allowed, as it has to point out the general objects we should all have in view, and how some of these may be obtained by the studies recommended, while the subsequent lectures keep more closely to the subject of those studies. M. Caesar Daly published a pamphlet on "High Studies in Architecture," which has been largely circulated among architects. He accuses all the various French schools of not devoting any serious attention to this subject. As the French schools are very like our own, I may give his enumeration of them. The Paris School of Fine Arts, the architectural schools of Paris and the provinces, the school of Rome and of the diplomaed, the diocesan—i.e., Gothic, which he says knows most about the history of the styles that it cries up; the Independents, and the "Don't care a d—" school. I do not think this is the time to discuss all his propositions, but there are two or three which will, I think, be both interesting and instructive—namely, the programmes for the Bordin and Duc prizes. That for the first is:—"To seek if there be a common æsthetic law, applicable to the monuments of the great epochs of art, and from this point of view to study the monuments of the Egyptians, Greeks, Romans, and those of the Middle Ages, of the Renaissance, and of modern times to the end of the 18th century." This study is not without its use. A clever and indefatigable student might possibly discover laws that have hitherto been overlooked; but one can scarcely hope that one law can be discovered that would insure success in every building, no matter what was its style; we should then have discovered the philosopher's stone of architecture. M. C. Daly says: "Englishmen are practical." So I think, without going so far afield. Those who aim high may be recommended to take the best of each of the different sorts of buildings in the style which each one affects, obtain their size, and then carefully calculate the general proportions for the general effect, and the particular proportions for the particular parts. I have mentioned here before that Sir C. Barry's Reform Club was designed, so far as general proportions go, on an average of those found in the principal Italian palaces, and it is certainly one of the finest proportioned buildings in England, if not in Europe. There can, I think, be little doubt that the Greeks, Romans, Byzantines, Saracens, and Mediaevals had some rules for the due proportioning of their buildings. M. Caesar Daly ventures to say that "architecture is a social expression." I say "ventures" because, as far as we can see, different nations at different epochs had but one chance—i.e., the style in vogue—though there must have been some passion in each nation, or in the architects as a body, to produce those modifications whose ultimate developments we call styles, and those peculiarities we call schools. At each epoch there must have been a taste for some particular characteristic—i.e., for massiveness, exquisiteness, or magnificence, for height or for width, for complexity or for simplicity, as well as a marked liking for particular features, such as the pediment or gable, the arch, the vault, the dome, or the tower, though the arch was an economic invention, and the vault was a preservative from fire. Cicero thought there must be pediments in Elysium; Procopius is never weary of praising the dome of Sta. Sophia, "pendent by subtle magic." But who can say now that there is a predominant admiration for any particular form of architecture? The programme of Joseph Louis Duc's prize is as follows:—"To determine by special studies the style of modern architecture." In the ordinary sense one would say that it is every style and no style; but there can be no doubt that every modern building which is not a copy, and few are copies, has a 19th-century air about it. We cannot imagine Ictinus or Mucielés saying of one of our Grecian buildings, This is Greek. Cossutius or Vitruvius would not say of our Roman buildings, These are Roman; nor would Villard de Honnecourt, or William of Wykeham, say of our modern churches or cathedrals, These are Gothic. They would all probably say, These are not our Architecture; but I cannot admit that this flavour amounts to a style—it is only fish, flesh, and fowl

with 19th-century sauce. For the architecture of to-day to claim the designation of a new style, it must have adopted new forms by reason of new wants or new materials, or it must have embodied in its buildings the aspiration of the people, so that each building is so permeated by it as to give them all a family likeness; but, alas! the people had no aspiration to embody. Eclecticism itself would constitute a new style if all pillaged the same things and arranged them more or less in the same manner. I gather from M. Caesar Daly that Duc expected that the competitors should attempt to show the new style in their designs. No man can create a new style, though, if he be a great genius with a strong personality, he may considerably modify the existing one. As far as we can now see, styles gradually grew up; certain things, or certain new forms, were wanted, and in striving to get these some parts had to be modified. We see in the Roman baths how the entablatures were cut through by the large arches, and were thus obliged to be mitred round each column. The long entablature perished, and with it the prevalence of horizontal lines connecting the columns, and in its place are isolated columns with a scrap of entablature over each, so that the prevailing principle was verticality. In Diocletian's Palace (probably built about A.D. 305) we see that the architects had got tired of sham lintels, and, where they could, used round arches in their place. The architects found, too, that mitred entablatures on isolated columns were in the way where arcading was used, so, when it could be managed, the arches were made to spring either directly from the caps of the columns or from blocks on them. Small colonnades or arcades, when used as decoration only, were carried on corbels, while the traditional ornament was still carried out to the best of their ability. In 532 A.D., some 200 years later, Justinian had Sta. Sophia built; then all traces of entablature over the columns had gone, and it had taken its place over the arcades. The capitals take a new form, and are enriched with a new scheme of ornament, and the dome rests on pendentives. Anthemius of Tralles was doubtless the great architect of his day; the possessor of the current traditions and practices, and had without doubt used pendentives before on a small scale. The Koptic architect who built the brick mosque for Touloun in the 9th century, 876 A.D., at Cairo, was merely possessed of the Byzantine traditions, as carried on in Egypt, and possibly was the inventor of the small arches that take the place of pendentives in the dome. His successors gradually worked out these arches into the form of stalactites that were so much affected, until at last we get the Alhambra and the Alcazar, which scarcely bear any resemblance to Byzantine work. The Romanesque architects, who eventually developed Gothic, went to the Crusades, saw the principal buildings in Rome, Constantinople, Asia Minor, Syria, and Palestine, and either from being prisoners themselves, or from intercourse with Saracen architects who had been taken prisoners, became possessed of the geometry, so much cultivated by the Saracens, and also adopted their methods of design, particularly in producing effects by the constant repetition of parts. So I think we may say that new styles are developed in the course of ages, from the introduction of new methods of construction, new ideals, and, to some extent, through the love of new forms of ornament. In the present day iron, in the form of cast iron, wrought iron, and steel, is insensibly affecting architecture—I mean stone and brick architecture—for scarcely any large building solves all its problems without the use of iron. As far as buildings of cast-iron go, there have been no great achievements yet, within the pale of architecture, and as far as wrought iron and steel go, none. I do not say that nothing has been attempted, but no success has as yet been achieved, and for these reasons, that it has hitherto been too costly to mould wrought iron and steel, and buildings have not been big enough to use the ready-made forms as units of enrichment, nor have artistic gifts been found in the engineers. When good effects have been attained, they have been attained by chance. I do not complain of this, because, in most engineering structure, the main difficulty has been to do them at all. I think we cannot help noticing that there has been an effort at the Paris Exhibition to try what can be done with these materials so as to bring them within the pale of architecture. A witty English architect described the Eiffel

Tower as "a factory chimney in lace,"\* but this is an engineering work, its claim to our admiration is rather founded on the solution of a problem in construction, that was looked on as insoluble, than as the solution of one in beauty; this was at most considered to be of slight importance. The treatment of cast-iron at the Exhibition buildings at Paris, in the shape of columns, has been so successfully achieved as to make the columns perfectly harmonise with the decorated wall they carry; for we have now become so well acquainted with the strength of cast iron as to tolerate its bulk being small, in proportion to the weight it has to carry, and in this case the contrast is agreeable. I cannot too much praise those flanks of the Exhibition buildings where cast iron has been used for support in association with mouldings, sculpture, mosaic and colour; but when it was wanted to bring wrought iron within the pale it defied solution. All honour to the attempt! The wrought-iron stanchions, filled with terracotta, only suggest that the terracotta has been thus packed in iron crates for travelling by rail. In the domes the ribs are unobjectionable, by reason of their slowness; they are mere cobwebs. M. Dieulafoy's spoils of Darius's Palace have taken root and blossomed, for the external domes of the Exhibition in coloured and enamelled bricks are a lovely invention—I think it may be called an invention, in spite of its traditional use in Persia. The adoption of coloured and enamelled bricks for the roofs of vaulted and domed structures, possibly even of ordinary pitched roofs, would add much to the beauty of modern cities. I think I am not singular in looking on the Royal Academy as being desirous of encouraging the higher studies. It does not so much profess to teach that alone by which the student may get an honourable living, as to try to fit him for the highest employment—i.e., the designing of grand public and private monuments, monuments that by their durability and beauty may give a notion of the magnificence and taste of this day to succeeding generations—may, whose very ruins may speak of the greatness of our time, and give lessons in taste, planning, and construction to future architects, when even our language has become the province of a few scholars. No architect should forget that some ruins still excite our admiration, though the written language of their builders is incomprehensible. I may instance the Pelasgic and the Etruscan. I think I may here interpolate a maxim: Never allow your indignation or despondency to prevent you from still doing your best when you have been thwarted in your favourite schemes—always think of Wren. Your indignation and despair will end with your life, even if they last so long, while your building may last for centuries; let not the future cultivated student of your building say, "The architect of this was not steadfast to the end." I will now give you a slight sketch of what we know about the Roman houses and palaces, and of what we may gain by the study of them. Most of the private houses of the Romans have been utterly destroyed, except those in Herculaneum and Pompeii, and we may at present exclude the former from our consideration, as so few have been excavated. It was only after the publication of Sir W. Gell's "Pompeiana," at the end of the first quarter of the present century, that much was known about the houses of the Romans except to those who had seen the excavations. Since his day many splendid monographs have appeared on the subject; the works of Zahn, Müller, Mau, and Niccolini have become textbooks. The plan of Hadrian's Villa, near Tivoli, taken by Pirro Ligorio, was published in 1751 by Contini, and Contini himself published another in 1768. Robert Adam in 1764 published his restoration of the Emperor Diocletian's Palace at Spalatro,† in Dalmatia. Guattani gives the Palace of Augustus on the Palatine in his work of the "Un-edited Antique Monuments" in 1784, and Constantine Thon and Vincenzo Ballanti gave their restorations of the Palace of the Cæsars in 1828, though but a part of Nero's golden house is included. Plans of the Palace of the Cæsars since the recent excavations were published in the *Revue Archéologique* by M. Deglane, in 1888. Mr. Charles Lucas told the editor, M. A. Levy, that I was about to lecture on the subject, and out of compliment to the Royal Academy he presented

\* Mr. J. J. Stevenson.

† Spalato is the modern name; but Adam calls it Spalatro.

me with a copy. As regards the palaces, though the ruins of the few I mention remain, we are even more at fault in them, than in the baths; we have no knowledge of what the rooms were used for; we learn, however, from Epictetus that some of the sumptuary trades were probably carried on in the palace of the Cæsars, for he tells of Epaphroditus' slave, the cobbler, who got a place as Nero's shoe-maker. Guattani gives us plans of the two stories of Augustus' house, which was of a very moderate size. Suetonius tells us it was originally the house of Hortensius the orator, who was married to Cato's wife; but it was probably altered and enlarged, if not rebuilt by Augustus. I cannot say what authority there is for identifying it with Augustus. The front rooms on the ground floor have a Byzantine air about their plans, and Guattani says the shapes are unique. In looking at the plan, we cannot help speculating in which room it was that Augustus gave his fancy-dress supper party, where he and his guests personated the gods and goddesses of Olympus, greatly to the scandal of the good people of Rome. Tiberius and Caligula built larger palaces alongside this, and Nero extended his golden house from the Circus Maximus to what is now the Theatridion of Titus's Baths. I do not know what it cost; but the Emperor Otho gave three millions sterling to finish it, the Colosseum being built on part of it by Vespasian. Domitian added to the Palace one of his own, mainly consisting of state rooms. Hadrian also built a palace, and Septimius Severus, a portion of which was so lofty as to be commonly called the Septizonium, although something of that name existed near the place when Titus was born.\* Hadrian's Villa, near Tivoli, is of immense extent; but was a sort of model of all the celebrated buildings and places he had seen, as well as a palace for himself. Diocletian's Palace, or rather Villa—for he was an ex-Emperor when he lived in it—was of moderate size for those days; it only covers about 9½ acres, and holds about half the modern town of Spalatro. It is mainly interesting on account of its being a point of transition between Roman and Byzantine. We are as ignorant of the uses of its rooms and halls as the uses of the rooms in other palaces. Should I find time, I will touch on the palaces hereafter. As these lectures are useless for architects if they do not give indications of studies that may further them in the exercise of their profession, I think it will be well to say something of the advantages that I think may be gained by the study of Roman houses, villas, and palaces, and their restoration. I have told you what I think may be gained by the study of Roman plans. Confining myself now to the private houses and villas, let us see what these can teach us. Not long ago the President pointed out the distinction between the present day and the days in which Pompeii flourished, that while all our utensils are merely utilitarian and all alike, everything in Pompeii, down to the meanest vessel used in the kitchen, was a work of art, and that the bulk of those used for the same purpose were different.† Even to familiarise ourselves with the utensils would be a considerable gain; but in studying the architecture we have, I think, a double advantage: we find that an entirely different method was adopted for public and for private buildings. For example, the architects of Pompeii would never have reproduced a Doric temple on a small scale for a porter's lodge, as was done here a few generations ago. The architects, too, were much freer in their treatment of well-known parts in private houses than where these were to be used in public buildings. We see, too, at Pompeii every building nearly complete, the mosaic pavements on the floors, and in conjunction with the painted architecture and decoration, the places where there was water and where fountains played, the pedestals or niches for vases and statues, and, in fact, nearly everything as it existed in the first century of our era, except the people, the awnings, the coverings, the carpets, the couch covers, and the curtains; and how splendid these last were we read of in Martial and Petronius. We are too apt to picture Roman buildings as white, and peopled with white-togaed Romans; but very early in the Empire the white toga was rather the exception than the rule, and as each considerable person travelled through the city in his sedan chair, he was attended by hosts of slaves of all colours,

and as richly equipped as their master's purse would allow. Public buildings, too, were less white than we imagine they were; they were rich with coloured marbles, precious stones, bronze, silver, and gold, and with gorgeously coloured and embroidered hangings. We are apt to fancy from the remains of public buildings that strict uniformity was the rule in the capitals of columns and in other ornament, while in private houses we see the capitals at least full of variety and invention. We think, too, that the architects of the Early Italian Renaissance were gifted with an affluence of invention scarcely met with before or since, while in reality almost everything in Renaissance days was paraphrased from Roman remains when it was not directly copied from them. You have only to look at the remains in the Vatican Museum and in the Roman villas to convince yourselves of it. All the arabesques of Raffaele and his school were at least inspired by those found in the chambers of Nero's golden house, below the Baths of Titus; and the stucco designs of the Villa Madama were copied from Hadrian's Villa. In studying the Roman houses and palaces, and still more in restoring them, we become acquainted with the Roman method of planning, with the proportions adopted, with the manner of finishing the work, with the scheme of their sculptured enrichments, with the scheme of the colour and of the colour decoration, and while studying these, we should naturally avail ourselves of all the hints that might be got from the shape and ornamentation of the furniture and utensils. I would ask if the fact of being steeped in this artistic medium is not likely to improve you artistically, and give you both a greater capability of doing artistic work, and a greater desire to see your employers use it? Is not the absence of artistic surroundings the great want that the artist has to encounter in England?

#### BOOKS RECEIVED.

THE Edinburgh Architectural Association have just issued the first part of a volume of *Transactions*, in the form of a paper-covered book of 50 pages, containing short notices of the various buildings visited during the session 1888-9. It is illustrated by page wood engravings of Neidpath and Drochill Castles and by several plans. The 31st annual report of the Council, which is appended to the volume, states that 30 names have been added to the roll of members, while three died, and 23 have resigned or withdrawn, leaving 297 names on the list. As an experiment the *Transactions* promise well, and will be valued by members, but an index would be a desirable and is indeed a necessary addition. — *Sewer Ventilation and Sewage Treatment*, by R. HARRIS REEVES (London: Sinclair, Tweedie, and Co.), is, the author frankly states, expressly written to bring his system before the public. This system of deodorisation by chemicals and ventilation of sewer air has been tried at Tottenham and Frome, and the writer claims for the trials satisfactory results, but he does not state the principle upon which he works, nor the chemicals used, neither does he quote the approximate cost per head or per thousand gallons.

#### BRICKS AND BRICKMAKING MACHINERY.

By M. POWIS BALE, M.Inst.M.E.; A.M.Inst.C.E. Author of "Woodworking Machinery," "A Handbook for Steam Users," &c.

#### BRICK-MOULDING MACHINES FOR THE PLASTIC PROCESS.

THE brick-moulding machines usually employed in the plastic process of making are known under the general title of "wire-cutting machines," so called because the stream of clay, after it has passed from the machine, is cut into lengths suitable for bricks by means of a series of wires. These machines are made of different sizes, types, or combinations to suit the varying circumstances of manufacture, and are known as four, three, two, and one-process machines, according to the number of operations combined in and performed by one machine. The modus operandi of a four-process machine may be briefly described as follows:—(1) Hoisting the clay, (2) crushing the clay, (3) pugging the clay, (4) moulding the clay into bricks. Operations No. 1 and 2 are often performed by separate machines, as

described elsewhere. In this case the moulding machines are known as three or two-process machines. In a four-process combination machine the clay is hoisted by means of a chain and suitable winding gear drawing a truck up an incline to a platform above the crushing rollers, which are placed at the top of the machine.

The clay which has already been weathered or prepared, is shot from the truck into the crushing rollers, through which it passes into a pug-mill usually working horizontally, in which it is thoroughly tempered and is finally forced in a continuous stream through a die of the size and shape of the brick required. The stream of clay is then received on a brick-cutting table, and cut into lengths by the wires already spoken of. The bricks are then removed on boards or bearing-off barrows to the drying sheds, from which they pass to the burning kilns.

The principle on which all wire-cutting moulding machines are constructed is very similar; they, however, vary considerably in constructional details. The pug-mills are arranged both horizontally and vertically, as convenience may dictate, and are usually fitted with single or double Archimedean screw-blades for feeding the clay onwards. The chief difficulty found, however, is to keep up a constant and even stream of clay to completely fill the die; in fact the die and its feeding are without doubt the most important points about the machine, and considerable ingenuity has been exercised by makers in overcoming these difficulties, and we propose to give descriptions of several of the most approved forms of dies. The ordinary screw-pug feed is the most common, and to get the required pressure on the clay to force it through the gradually tapering chamber and die, it is necessary to fit a propeller or one blade of the screw feed at the extreme end of the pug-mill shaft. Another plan is to force the clay through the die by means of compressing rollers.

In some of the earlier machines, the clay was forced by the pug-mill through a die with well-rounded corners—so rounded to reduce friction and permit of the easy passage of the clay. After the clay had passed the die, it was drawn through the vertical and two horizontal rollers which were driven and squared its edges, and passed it in a continuous stream to the cutting table, where it was divided into bricks by means of knives or wires. In this case the clay was drawn instead of being forced through the roller, which acted practically as a rotating die.

To insure the passage of a constant and even stream of clay through an ordinary fixed die, pistons have also been employed. In one machine a piston, driven by a screw and bevel gearing, forces the clay through a die sufficiently long to form several bricks, and this is divided longitudinally and transversely by a series of knives.

An arrangement used in America is to form the pug-mill feeding screw and die in a horizontal line and of conical shape, the end of the screw being made with a gradually increasing depth of thread up to the die, the chamber just before the die being roughened to prevent the revolution of the clay. After passing the die the clay is delivered on the endless apron to a knife worked by a flywheel, arranged to make its cut and divide the clay at regular intervals into bricks. A second apron running at an increased speed is used to carry the bricks away.

It need hardly be said that whatever form of feed or die be used, it is of the utmost importance, in order to secure a successful result, that the clay be fed into the machine constantly and evenly, any irregularity in this respect very soon showing itself in the quality and quantity of the bricks turned out. The clay, too, must be thoroughly homogeneous, and neither too stiff nor too soft: the amount of water to be added to effect this result can only be ascertained by experiment, as some clays require very little, and others a good deal.

Our illustration, Fig. 5, represents a four-process brickmaking machine, from the designs of Messrs. John Whitehead and Co., of Preston, a firm who have devoted many years to perfecting machinery especially adapted to the plastic system of making. The four operations combined in the machine are: (1) hoisting the clay, (2) crushing, (3) pugging, (4) brickmaking, or moulding.

The hoisting gear is arranged to bring the clay up an incline to the crushing rollers, and is fitted with a clutch and lever for throwing in or out of work, and friction belt and brake to regulate the speed of the empty waggon down the

\* Suet. "Titus," cap. I.

† Presidential Address of Sir F. Leighton, Bart., Art Congress, Liverpool, 1888.

Fig. 5.

incline. The crushing rollers are thrown in and out of gear by means of a sliding clutch and lever, and are fitted with wrought-iron slide plates and adjustable steel scrapers. A self-acting friction belt, to prevent breakage of wheels, in case of the accidental introduction of uncrushable materials, is also fitted.

The machine illustrated is a double-delivery one, and, after passing through the crushing rolls, the clay enters the pug-mill, where it is reduced to one consistency, and forced onwards in a continuous stream through the dies on to the wire-cutting tables, where it is cut into bricks. The pug-mill is made in two parts, flanged and bolted together, so that the upper part may be readily removed for the adjustment or repair of

the pug-mill shaft and blades. We shall have something to say with reference to the cutting table elsewhere. By changing the linings of the dies, bricks with ornamental moulds, bull-nose, bevelled and other shapes, may be produced as readily as plain bricks, and by substituting pipe dies drainage pipes also. Taken altogether, this machine bears evidence of great care in designing, and must be pronounced a very favourable specimen of its class.

Mr. W. H. Radford, C.E., of Nottingham, has been instructed to prepare plans for intercepting sewers and sewage precipitation tanks at Oundle. Mr. Radford was recently the successful competitor for a scheme of waterworks for that town.

The annual meeting of the Royal Scottish Society of Painters in Water-Colours has been held at Edinburgh. Mr. Francis Powell, R.W.S., was re-elected president, Mr. William M. Taggart, R.S.A., vice-president, and Mr. Hamilton Maxwell, treasurer. Mr. J. Wright Robt. was appointed secretary in place of Mr. Smith (one of the founders of the society), who has resigned, and was elected honorary member.

New stalls of teak, and a reredos, altar, and super-altar in oak, together with a piscina in English alabaster, have been added to the fittings attached to the Home of the Good Shepherd in Uxbridge-road, W. The works have been executed by Mr. Harry Hems, of Exeter, from designs by Mr. Thomas Garratt, of Shepherd's Bush, the original architect of the chapel.

## ROYAL ACADEMY PRIZE CARTOON FOR DECORATION.

This double-page plate represents the full-size cartoon of the central group of figures from the Royal Academy prize design for the decoration of a public building, by Miss Gertrude Demain Hammond, of Clapham, who has been commissioned to carry out the work by the Royal Academy of Arts. The commission to execute such prize designs has only been given three times, and Miss Hammond is to be congratulated as the first lady student to be thus honoured, both the previous commissions having been given to men. The subject of her admirable design represents a vine harvest festival in honour of Bacchus, and it has the inscription "Evoc Bacche Io! Io! Evoc! Iacche!" As to the general scheme of colour, it might be called a combination of white and warm yellows and greyish pinks, the whole against a grey, partly shadowed, marble wall and pillars, with a soft, yet brilliant blue sky seen between. We shall, at an early day, publish a double-page illustration of the whole composition, which we described and praised when reviewing the whole of the Royal Academy prize designs on the occasion of the award last month.

## NEW PALACE HOTEL, PRINCE'S-STREET, EDINBURGH.

This building was opened in June last, and consists of considerable alterations on, and additions to, the late Caledonian Hotel, which entered from Castle-street. The portions between the oriels up to the level of the third floor are what remain of the old walls, and the shops also are old. It is to be regretted that several causes at the time operated to prevent the entire removal of the old front walls and the enlargement of the building by bringing forward the line of the new ones. The arrangement of the rooms on the upper floors follows that of the first floor, nearly all of them being arranged to let *en suite*, and all have double doors between. The stone used for exteriors is from Prudhome Quarry, Northumberland, and for stairs from Hailes Quarry, near Edinburgh. The passenger lift has been fitted up by the American Elevator Company, London; it works by hydraulic pressure, and gives great satisfaction. The architect is Mr. J. Macintyre Henry, 13, Frederick-street, Edinburgh, and the builders were Messrs. W. and D. McGregor. The total cost of the work has been between £11,000 and £12,000.

## THE "HOGARTH" CHIFFONIER AND "HADDON" CHIMNEYPIECE.

The first of these pieces of cabinetwork is being made just now for a house at Chiswick, near

where the great painter used to live. It is intended for a dining-room, the lower part being contrived for glass and cruets, &c., in daily use, and the large, deep drawer in the centre for the table-cloth and serviettes. The middle glazed cupboard above is well lighted for the display of old china and works of art; the side cupboards, with shifting shelves, are for books. The top has a flush top for placing large vases upon, as shown in the sketch. The simple lines adopted in this article of furniture are intentionally severe. The material is mahogany, with ivory knobs to the drawer. The piece stands on ball castors. The "Haddon" mantel, made in oak, explains itself. It has a cupboard for pipes and the like over the chimney-shelf. A marble slip inside the woodwork incloses the tiles round the grate. It has been placed in Messrs. Smith and Sons' premises, in Conduit-street, W. Both the above were designed by Mr. Maurice B. Adams, for Messrs. Foster and Cooper, of Nottingham, who have carried them out from the architect's full-size details.

## BRISTOL POST-OFFICE.

The head Post-office at Bristol has recently been doubled in size to meet the growing requirements of the service. We give an illustration of the elevation as now extended. The work has been carried out in the same style as that of the original building, the materials used being Portland stone for the cornices, copings, and strings, Bath stone for the ashlar, and Cornish granite for the plinths. The new block contains, on the basement floor, accommodation for the R.E. telegraph mechanics, store-rooms, boiler-room, &c. The ground floor is occupied by the large public office, in which all branches of the business are dealt with. On the first floor there are cloak-rooms and dining-rooms for the large staff of employees, and also minor offices occupied by the correspondence department. The instrument room occupies the whole of the second floor over both blocks, and at the back there is an annexe devoted to sanitary offices, kitchens, cloak-rooms, &c. The extension has been carried out under circumstances of great difficulty, consequent upon the necessity for avoiding interruption of the postal and telegraph services while the work was in progress. The contractor is Mr. A. J. Beaven, of Bedminster, the fittings being supplied by Mr. Jno. Reed, of Sutton Harbour, Plymouth. The fireproof construction is by Messrs. Dennett and Ingle.

## THE ALEXANDRA ARCADE, SWANSEA

THIS building, comprising some sixty-six shops, with offices and dwelling-houses, has been carried out from the designs of Mr. Edward Bath, architect, Swansea, at a cost of about £18,000. The Arcade connects High-street with Alexandra-road. The High-street elevation at present consists of three shops and dwelling-houses, and that of Alexandra-road of nine shops, dwelling-houses, and offices. The width of the arcade is 15ft. on the ground floor; but the first-floor shops have been set back so as to allow for a balcony or promenade round, 6ft. wide, which is connected with three bridges. The height of the Arcade is 35ft. A back entrance has been arranged for each shop. The conditions of the lease required the buildings to be as far as practicable fireproof, and the whole of the Arcade, shop-fronts, and roofs is constructed entirely of iron, while the roofs over the shops are of flat fireproof material. The buildings are lighted throughout with electric light on the Crompton-Howell system. The contractor for the buildings was Mr. Henry Billings, of Swansea, and the ironwork was intrusted to Messrs. W. McFarlane and Co., Glasgow.

## PULPIT FOR HOLY TRINITY CHURCH, ABERYSTWITH.

THIS pulpit, of Perpendicular character, is constructed of Welsh oak. The plan of the upper part is in the form of a pentagon, and the base is of solid work. The cornice, moulding, and panels are decorated with foliage somewhat naturally treated, the panels being alternately filled with pierced carving, representing the vine and the oak, and each contains a shield displaying some sacred emblem. The carving and construction of the pulpit was carried out by Mr. Cavendish Lemon, sculptor, Aberystwith, and the architects are Messrs. Middleton, Prothero, and Phillott, of Cheltenham.

## HISTORIC TOWNS.\*

OF the handbooks edited by Professor E. A. Freeman and the Rev. William Hunt, M.A., in Messrs. Longman and Green's series already published, few can have greater interest to the student of the growth of English cities than the one on Winchester, written by the Dean of that city, G. W. Kitchin, D.D., F.S.A. The earlier history of Winchester, its Roman occupation, its state under the Danish rule, are but briefly sketched, Dr. Kitchin's narrative being mainly directed to give an outline of the city's growth to the time of Henry I., when it attained its highest position, and its decline towards modern times. Winchester under the Romans is borne testimony to by the coins, vases, tessellated pavements, and other products of the 3rd and 4th centuries, and also by the Roman masonry of Wolvesey. Venta-Belgarum, as the city was then called, became the capital of the south of England. Its plan was rectangular, its base to the river Itchin, having the present High-street, its main thoroughfare, bisected by another road from South-gate to North-gate. Through the latter the roads to Silchester, London, and Cirencester led through West-gate, one towards Sarum through South-gate, one to Clausentum. At the top of St. Catharine's-hill entrenchments which surrounded the castrum may be traced. We have mention of Cerdic and Cymric, the former of whom died in 554, and was buried at Winchester, which became capital of the West Saxon kingdom. Cenwalh built the first cathedral and monastery, but no vestige remains—no doubt, on the site of the old Roman church. As yet there was no Bishopstool. Under Egbert (802), Winchester made rapid progress, and his bones still repose in one of the chests in the choir-screen. We have notice of the Norse invasion. St. Swithun, of whom legends are told, did much for the city. He fortified the cathedral, and rebuilt much that is still handed down to his memory as a pious man of "laudable qualities." It was between 901 and 940 that Edward the Elder completed the New Minster between St. Swithun's Church and the High-street. After Ethelstan, St. Dunstan appears as a great founder of churches and monasteries. The monastic revival between 940-975 is sketched, references are made to the reforms of Ethelwold, Bishop of Winchester, to Edgar's charter, the cathedral, the wonder-working St. Swithun, the popular translation of the saint and his miracles, the legend of the forty days of rain. The Danish invasion and reign of Cnut, 975-1035; the Norman conquest of Winchester, Williams' new palace, the new cathedral church of Walkelin, which was fourteen years in progress, are later events. Of the latter building the transepts of the present edifice and the walls and piers of the nave, encased by Wykeham, remain. The squat tower is a later Norman rebuilding, the original one of Walkelin having fallen in 1107. The ground plan and features of the Roman Lady-chapel also can be traced in the crypt below the beautiful later work of Hunton and Silkested. Dr. Kitchin briefly sketches the progress of the city under the Norman kings; a map of Norman Winchester being given, its condition as a Mediæval city, the days of Henry de Blois, the famous bishop (1129-1171), and its position under the Angevin kings. Later chapters, which we cannot notice here, treat of the disorderly scenes under Henry III., the swarms of Provençals who came over, and the later troubles of the city—all told by one who has made the subject a labour of love, and has constructed the narrative from original documents.

At Friday's meeting of the Middlesex County Council, a committee reported that plans for altering the Guildhall at Westminster, and converting it into a suitable sessions house and council chamber, had been considered. In the basement it was proposed to construct cells, jury rooms, witnesses' rooms, and offices, &c. On the ground floor there would be offices for the council's officials, robing-rooms, and two courts. On the first floor there would be a council chamber, 27ft. by 41ft.; also a library and writing-room, a large committee-room, and a magistrates' luncheon room. The committee recommended that they be empowered to have full plans with detailed elevations prepared. The recommendation was agreed to, the chairman stating that the council would not be bound to carry out the plans.

## WAYSIDE NOTES.

AN hôtel-de-ville for London, worthy of the great city, has been often acknowledged to be a desideratum—a genuine long-felt “want”; and in spite of the present unpromising outlook, there is no doubt that at some distant date an architectural feature of this nature will be very much in evidence in one or another of the more grandiose thoroughfares of our modern Babylon. There are, I suppose, plenty of persons who would undertake to prove that such a building, though all very well in theory, is in practice an impossibility. In a smaller city, they might say, divers different departments may be grouped together and housed under one roof; but in London each department is in itself so extensive as to require a separate building for its accommodation. As an architect, however, I turn a deaf ear to such arguments, and maintain that the members and officials of the County Council, at any rate, should be housed with becoming dignity.

The sooner some scheme for providing this building and supplying the long-felt want is matured the better for all parties concerned, not to mention the architectural profession. Year by year we are invited to compete for town halls and municipal buildings here, there, and everywhere; big Manchester, and smaller Manchesters of the North, get their palatial municipal offices; fair architectural compositions grace the smallest and least pretentious of towns in the British Isles, and still no call comes for such a building for the great metropolis with its odd 4,000,000 of inhabitants. The matter is talked of, but nothing comes to pass. Desultory discussions, such as that holden by the County Council at its two first meetings for the present session, though serving to keep the subject before the public, will do nothing to produce the wished-for municipal buildings; neither does the present council seem to have the heart to deliberately weigh the matter. By its action in patching up the old Spring-gardens nest, it has debarred itself from serious consideration of the whole subject. The truth would seem to be that before our municipal buildings are designed, let alone erected, there must be some degree of popular enthusiasm—a wide-spread and genuine enthusiasm, such as does not manifest itself to-day. Whether there ever will be this ecstasy among the worthy burghers of London-town remains to be seen. The architectural pessimist will shake his head dubiously. If it be impossible and against the nature of a congregation counted only by millions, then the Hôtel-de-ville of London will be ever in the *non est* state, or prove only some unworthy specimen of the architectural genus *Municipal Building* of which a decent provincial town would be ashamed. If, on the other hand, it is both possible and probable, then some day may be erected a building to which the London citizen may point with honest and manly pride.

In the matter of “wholesale contracts,” I agree with every word you say in your leader of last week. The interest of an architect increases two-fold on a work where, in place of a contractor anxious chiefly, and naturally enough, to make his contract “pay,” the works are executed, to all practical intents and purposes, by his clients. Architect, clerk of works, foreman, and workman alike show an added interest in their respective duties. I can only re-echo your hope that the system may increase in favour where important public works are concerned, for nothing would more largely conduce to good building and architecture, or prove so remedial of many of the deplorable results of undercutting among tenderers.

Fortunately, there is to be noticed a growing tendency to distrust the wholesale contracting system where extensive buildings are concerned. Often during the last few years the owners of many of the larger hotels have erected the buildings themselves, under a competent clerk of works, and the result has been satisfactory, not only to the proprietors, but to their architects. As a recent example, the Brighton Métropole may be instanced. There has been no wholesale contracting on this building, which is now approaching something like completion, as regards, at least, the general carcass. I noticed whilst at Brighton at the beginning of the week that the process of cleaning down and pointing has been commenced, and the extensive scaffolding will soon begin to dwindle away.

From what I have seen of this building, I should say it is as solid a piece of workmanship as one could desire, and a silent witness to the success of the system employed. On Monday morning, before returning to town, I sallied forth at an early hour intent on making an inspection of the new hotel, and, on the strength of this inspection, to moralise herein on “wholesale contracts” and the like. But the clerk of works was not upon the job—unless that job was his breakfast—and not even the fact of my being “Wayside Note” writer in ordinary to the “B. N.” could soften the heart of the inexorable door-keeper I encountered. So of the works executed, I saw but little. When the P.R.I.B.A. learns this, he will, I am sure, grieve, and leave particular instructions at the Métropole that the next time we repair to Brighton, admission to the works may not be denied us.

My contribution to the recent discussion on Mr. Cates’s paper anent the Institute exam., will be in the direction of adding weight to the desire for some system of classifying the examinees. I have often said that this is most necessary and desirable, and was very glad to see that, at the Association discussion, the question was brought forward by Mr. W. Millard and Mr. R. N. Wilson. Give the student some hope of earning reward justified by his labours, and the examination will become very much more popular. The bitterest complaint of many of those who have gone through the examination has ever been that, although they have studied with exceptional ardour, and given a large amount of time to preparation, they have passed, to all outward appearances, with no more credit than those who have been too callous and inert to study and prepare. My own idea on the subject is that there should be, as at present, the first prize man; but that, in addition, there should be several grades or classes, with or without honours. The inauguration of such a measure would be a great inducement to honest study. As at present existing, many go in for the examination without an hour of preparation, and this of malice aforethought. Knowing that it is either a question of pass or fail, and that there is no chance of an intermediate state, they take the risk, and if sent to *pur-gatory* for a season—yclept, “relegated to their studies”—they are content to go through the same performance on another occasion, trusting to have better luck and scramble through the ordeal. This is not as it should be, and is a state of things that I believe would be remedied by the classifying of successful candidates in order of merit. Having adopted my original suggestion as to the splitting-up of the examination into three sections, would it be too much to expect the Institute to consider whether the further reform would not be a real improvement, conducive both to the popularity of the exam., and to its practical utility?

As regards the outcry for enlarged schemes of education, educating bodies are all very well in their way, and the more that is done in this direction the better for the students who can view such institutions in their true light, and not regard them as destined to make learning easy and strew their thorny paths with flowers. I would draw the attention of such persons to what Mr. Cates said in concluding the discussion at the Association about the value of *self-help*. Without a spirit of self-helpfulness nothing can be attained; and with it everything, be every educating body swept from the face of the earth. Those embryo architects who think otherwise may usefully study Smiles’s “Self Help,” and learn that all the great men of past ages have, to all practical intents and purposes, educated themselves, mainly in the school of difficulty, and often in that of extreme poverty. The modern craze for educating institutions of every sort, if properly cultivated should be an immense advantage; but one cannot help wondering at times whether their ultimate effect may not be an undermining of that spirit of self-help and strong individual effort to which, in the past, the English nation has owed all its greatness.

The ivy-plant, like fire, is a good servant but a bad master. As an accessory to architecture, it is at times, and when held in check, invaluable as an aid to the picturesque—more especially when the building is none too handsome, in which case the clinging creeper will hide a multitude of sins. On an old church a little ivy adds a great charm, and to realise one’s idea of

a true “ruin”—a truly picturesque ruin, that is to say—the plant seems indispensable. Without the expression “ivy-mantled tower,” novelists, including the great Scott himself, would have been minus a most expressive phrase wherewith to give point to a passage of sentiment. But, in spite of its merits as an aid to the picturesque, we know that, in its old age, ivy has a vicious habit of insinuating its manifold, branching arms into the cracks and crevices of a building, thus endangering its stability. When, therefore, this occurs in connection with an historical structure that has intrinsic beauty and interest in its architecture, the ivy must be destroyed, or it will destroy the building. There are not many who will sympathise with the *Leeds Express* in their complaint *re* Kirkstall Abbey, on which you commented last week.

Ivy is generally treated with too affectionate and lenient a regard. Few seem to realise the parasitic nature of the plant, and fewer still recognise how it fastens itself upon tree and building, like evil habits on the man, and ultimately effects their destruction. Ivy looks so innocent and delicate when young that we forget the deadly embrace it gains as it waxes older. One of the prettiest objects we may behold in the foreground, during a woodland walk, is the youthful ivy plant, spreading a few sprays of delicately-formed and brightly-tinted leaves against the rugged, purple bole of the oak-tree. The tree itself seems to caress and fondle it; yet awhile, and the plant covers bole and branches, and the life of the once sturdy oak is smothered in its deadly embrace. So, on both building or tree, ivy must be kept within bounds, or the ultimate destruction of either is merely a question of time. Those who would make excuses for the plant may say that cases occur where its thick stems support crumbling masonry; but this not the general rule, for the over-luxuriant growth of ivy undermines the stability of any building rent with the cracks and crevices of centuries of decay. GOTH.

## CHIPS.

Copthorne, near Fawley, Hants, the residence of Capt. Drummond, has just undergone very considerable alteration and enlargement at the hands of Messrs. W. and R. C. Light, of Portsmouth; Mr. Mitchell, of Southampton, being the architect.

Alexandre Protais, the well-known military painter, died in Paris on Saturday at the age of 63 years. He served as a soldier in the Crimea, and accompanied the French troops to Lombardy in 1859, experiences which suggested most of the subjects for his numerous battle-pieces.

The Nantwich board of guardians decided at their last meeting to extend the hospital at the workhouse, from plans prepared by Mr. Davenport, at an estimated outlay of £5,000.

On Sunday week Mr. and Mrs. W. H. Godwin, of the Ferns, Lugwardine, celebrated their silver wedding, and on the following Monday a very pleasing gathering took place at Withington, when Mr. Godwin entertained the whole of the employés of Messrs. W. Godwin and Son, encaustic art tile manufacturers, and their wives to dinner. The celebration of their silver wedding was taken advantage of by the employés to present to Mr. and Mrs. Godwin an illuminated address and an ornolu drawing-room clock, with tazzas to match.

At the last meeting of the School Board for Carlisle, a committee recommended that Mr. T. Taylor Scott be instructed to prepare a set of plans for schools in Brook-street for 850 children. To this an amendment was proposed that all architects having offices in Carlisle be invited to send in plans. The committee’s recommendation was adopted by seven votes to three, and it was agreed to pay Mr. Scott 5 per cent. commission.

The Warwickshire County Council have accepted the resignation tendered, through ill-health, of Mr. Lait, the county surveyor. The resignation will date back to the end of 1889, and the duties of the office, pending the election of a successor to Mr. Lait, will be discharged by Mr. Wilmot.

The *American Architect* remarks: The profession in Brooklyn, N.Y., has to mourn the loss of Mr. Charles Keely, son of Mr. Peter C. Keely, the architect of so many Catholic churches all over the country, and associated with his father in business. The practice of the office is enormous, fifty churches, it is said, being sometimes in process of execution from the designs of the father and son, and of the excellent work done there, no doubt much was due to the younger man’s talent. Mr. Keely was about thirty-five years of age, active and popular.

## CONTEMPORARY BRITISH ARCHITECTS.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

WE give our fourth double-page plate of photographic reproductions to-day, and have grouped together the portraits of six well-known architects, of whom the following particulars, furnishing a simple summary of their chief works, may be interesting as a record for future reference:—

Mr. James Piers St. Aubyn, F.R.I.B.A., whose photograph comes first on the sheet, was elected an Associate of the Institute in 1837 and a Fellow in 1856. His chief work in London was the restoration of the Temple Church, including his additions to that building. A large block of chambers in the Temple was erected a few years ago from his designs, and in conjunction with the late Mr. E. M. Barry, R.A., Mr. St. Aubyn built a larger group of similar suites of offices for the Temple authorities, overlooking the Thames Embankment, some time previously. He also erected the four district churches, St. James, St. Mary, St. Stephen, and St. Paul, at Devonport. St. James-the-Less, at Plymouth, is another of his churches, and at Reading he designed All Saints, St. Giles, and St. Luke's. Near Chelmsford two more may be named—at Widdford and Galleywood Common—as well as three other churches at New Brompton, Chatham, and at Erith. In Cornwall, where Mr. St. Aubyn restored St. Michael's Mount, he built churches at Marazion, Penzance, and St. Ives. Others, too, have to be mentioned, such as the church at Revelstoke, South Devon; church restoration at Woolverstone, near Ipswich; and the English church at Dresden. In Ireland, Mr. St. Aubyn erected a church at Kilmaloda, Co. Cork, besides numerous other new churches about England, not to name several private chapels and mission-rooms and church restorations in most of the western and home counties. A design prepared for Truro Cathedral by Mr. St. Aubyn was published at the time its erection was contemplated. In Cornwall, among this architect's mansions and houses, we may note Clonance and Pencalenick. Others are at Anstey, near Dorking; Slinfold, near Horsham; Muntham, also in the same locality; as well as Greenhurst, near Ockley, in Surrey; Delamore, South Devon; Curry Rivel, near Taunton; Chalcot, near Westbury. Claville, Minehead, Somerset, he built, and many less-important residences in Cornwall and other counties. The Theological College and new church at Ely are among Mr. St. Aubyn's works, and many restorations in that diocese. The Carillon Tower for twenty bells, at Abberley, and large additions to Abberley Hall, Stourport, were carried out from his plans, besides numerous parsonage houses in other parts. Mr. St. Aubyn has read practical papers before the professional societies at various times.

Mr. Thomas Blashill, the Superintending Architect to the London County Council, is a Fellow and Member of Council R.I.B.A., a past president of the Architectural Association, F.S.I., and Member of Council British Archaeological Association. He succeeded the late Geo. Vulliamy as architect to the Metropolitan Board of Works. Amongst his executed buildings are Christ Church, Beckenham; restorations at Stottesdon, Shropshire; Putley, Much-Dewchurch, Hampton Bishop, Dormington, &c., Herefordshire; schools at Tarrington and Yarkhill, Herefordshire; parsonages at Sutton-in-Holderness and Orlestone, Kent; the business premises of Messrs. Trübner and Co., Ludgate-hill; Ingram House, Fenchurch-street; enlargement of the Standard Bank of South Africa, Clement's-lane; and various works for the Guardians of the City of London Union. His literary work includes a Guide to Tintern Abbey, published in 1879, and he read a paper before the Institute in 1878 on "Oak and Chestnut in Old Timber Roofs." His pamphlet on "The Tenure of Land for Building" is well known, and also his lectures at the Carpenters' Hall on "Shoring," "Growth and Seasoning of Timber," and "English and Continental Doors"; at the Society of Arts on "Health, Comfort, and Cleanliness in the House"; at the Architectural Association on "Party Walls," &c.; and at the recent Art Congress, Edinburgh, on "The Influence of the Public Authority on Street Architecture." Mr. Blashill was a district surveyor for ten years, first of Bethnal Green East, and afterwards of West Hampstead, until appointed Superintend-

ing Architect of Metropolitan Buildings, about three years ago. He took an active part in the excursions to Italy held in connection with the Architectural Association, and he obtained a fore-man's share in the work of that society some years since. The photograph reproduced was taken by Messrs. Turner and Drinkwater, of Hull.

Mr. Lewis H. Isaacs, M.P., is a Fellow of the Royal Institute of British Architects, and an Associate of the Institution of Civil Engineers. He served his articles with the late Mr. Edmund Woodthorpe, and at the age of 26 received the important appointment of Surveyor to the Board of Works for the Holborn District, to which was added shortly afterwards that of Surveyor to the Honourable Society of Gray's Inn. Mr. Isaacs has been officially connected with and professionally concerned in the many public improvements which have been carried out in the Holborn district since he held office therein. These embrace the removal of Middle-row, Holborn, the widening of the northern end of Chancery-lane, the formation of Clerkenwell-road, the widening of Theobald's-road and Gray's Inn-road, and the formation of Rosebery-avenue, leading from the Holborn Town Hall to the Angel at Islington. His principal works in London are the warehouses and offices of Messrs. Geo. Farmiloe and Sons in St. John-street, the Charterhouse-street Branch of the London Joint Stock Bank, the Holborn Viaduct Station and Hotel forming the City Terminus of London, Chatham, and Dover Railway, the Paddington Public Baths and Wash-houses, and the large range of factories, warehouses, and showrooms built for the late Mr. Charles Cadby, pianoforte manufacturer, at Kensington. Mr. Isaacs also erected, conjointly with Mr. Florence, a mansion in Delahay-street, S.W., the town residence of Mr. Edward Lloyd, overlooking the Green Park. In 1877 Mr. Isaacs entered into partnership with Mr. H. L. Florence, F.R.I.B.A., which partnership existed until 1888. During that period the firm of Isaacs and Florence built, amongst other works, the Holborn Town Hall, a new Library for the Honourable Society of Gray's Inn, the Paddington branch of the London Joint Stock Bank, and the Hotel Victoria in Northumberland-avenue. Mr. Isaacs was elected M.P. for the Walworth Division of the Borough of Newington in 1885, and he was re-elected by the same constituency at the General Election in 1886. His photograph was taken by Mr. Vernon Kaye, of South Kensington, whose print we have reproduced.

Mr. Ewan Christian, the Architect to the Ecclesiastical Commissioners for England, which post he has held for more than thirty-eight years, is a Past President of the Royal Institute of British Architects, and a Royal Gold Medallist. On the occasion of its presentation in 1887, the recipient said: "Mine has been a life of independent service, not of exploits. I have undoubtedly done much work, and some I hope of a valuable kind to those most interested; but I could not think of comparing myself with many of the men of mark who have preceded me in receiving this distinction." To give a list or anything like a complete list of this architect's work, extending as it does back as far as 1840, would be impossible without considerable trouble, and it is beyond our scope to attempt in any case such a catalogue; but a few may be mentioned in the interests of our readers. Mr. Christian has acted as professional referee in numberless cases of church competitions, and he was chosen to adjudicate in the Edinburgh and Liverpool Cathedral competitions, as well as in the Admiralty Offices competition a few years ago. As the advising and acting architect, since 1852, of the Ecclesiastical Commissioners, he has had to report on plans submitted for churches and other ecclesiastical works, amounting on an average of ten years to about 218 yearly, and also upon the cathedrals of Chester, Durham, Lichfield, Canterbury, St. David's, Worcester, Ripon, St. Paul's (London), Carlisle, the last named having been restored by him; and upon Southwell Minster, the continuous restoration of which, intrusted to him for the last thirty years, is still unfinished. When Mr. J. J. Stevenson read a paper on Anti-Restoration before the R.I.B.A. some years since, Mr. Christian warmly supported the late Sir Gilbert Scott, R.A., on the occasion of his reply to the charges made by the anti-restorationists. Hildenboro Church, near Tunbridge, was one of his first works (1843), others, among some forty new churches, being those of St. Thomas, Douglas; St. John, Kenel-

wark, Kent; St. Stephen, Tunbridge; Christ Church, Forest-hill (recently completed); St. Luke, Marylebone; St. James, Leyland, near Preston; St. Peter, Rochester; Swanley Church, near Sevenoaks; St. Stephen's, Spitalfields; St. James, Tunbridge Wells; Trinity Church, Folkestone; St. Mary's, Carlisle; St. Mark, Leicester, St. Matthew at Cheltenham, and of All Hallows at Bromley-by-Bow. From among some 140 restorations of churches—from that of St. Mary, at Scarborough, to the little church at Skelton, near York, restored in 1886, though the monograph of it was published by Mr. Christian as early as 1846—may be cited those of Westwell (Kent), East Meon (Hants), Holbeach (Lincolnshire), Stanhope (Durham), Thorington (Essex), Bosham (Sussex), Alcombury (Hants), St. Dunstan (Canterbury), all interesting examples of Mediæval architecture; episcopal residences at Norwich, Gloucester, Manchester, Bishopsthorpe, Lambeth; caputular residences at Exeter, Llandaff, Bangor, St. Asaph, and in Amen Court for St. Paul's, London; rectories, vicarages, parsonages, and curates' houses of all grades built in every county of England (except Northumberland, Cheshire, and Cornwall), and in Wales, not fewer than 200 in all; numerous schools, and a still larger number of country houses, amongst which are Lavington Manor (Wilts), Abbotsford and Broadwell (Glos.), Lillingston Dayrell (Bucks), and Ascot Wood for the late Sir J. Shaw-Lefevre. "Castle Malwood," Sir William Harcourt's new house in the New Forest, is one of Mr. Christian's most extensive and latest mansions, and "The Highlands," Gloucestershire, also in half-timber, is another. Viney Hill, near Lydney, in the same county, in local red sandstone, was built by him in 1865. Among more recent works in London are the large bank in Parliament-street, erected for Messrs. Cox and Co., and the red terracotta block of offices in New Bridge-street, Blackfriars, for the Economic Assurance Company. Not a few convalescent homes, business premises, and other buildings have been erected under Mr. Christian's supervision all over England. His own house at Hampstead, "Thwaitehead," which he designed, was published among the series of drawings which we gave not long ago in illustration of "Artists' Homes." The new National Portrait Gallery, to be given to the nation, is to be built from this architect's designs, near Charing Cross. Lately Mr. Christian has been appointed by the London School Board to advise and report on the faulty construction of their school buildings, about which an inquiry has been held. His portrait was photographed by Mr. Barraud, of Oxford-street.

Our next portrait is of Mr. William White, F.S.A., who can reckon amongst his works about 120 private houses; 90 school and schoolhouses (70 new); 80 parsonages (45 new); and nearly 250 churches (about 60 being new or rebuilt)—six of these were erected at Battersea. Amongst his principal works are: Truro bank and solicitors' offices; St. Columb bank; renovation of ancient and interesting rectory houses of St. Columb, Cornwall, and of Dartington, Devon; renovation of ancient episcopal palace and chapel of Bishops-court, near Exeter; vicarage house and parochial room of St. Mary Abbott's, Kensington; mansion at Humewood, Co. Wicklow; masters' houses at Winchester College, Eton, Rugby, Shrewsbury, Repton, and Marlborough; Andover cottage hospital; fever and infection hospitals at Winchester College—the plans for which received the highest award (silver medal) for "School Sanatoria" at the Health Exhibition; Hertford public steam laundry; church of All Saints, Notting-hill; Lyndhurst church in the New Forest; St. Saviour's, Aberdeen Park, Highbury-grove; Madagascar cathedral, just completed; and Pretoria cathedral, plans for which are now ready for commencement. Mr. White has written much on Architecture, including "Notes on Newland Church, Gloucester"; "Ironwork, its Use and Treatment"; "Ancient Lights"; "Domestic Plumbing and Water Service"; "Fireproof Construction," and "Wisby in Gothland." He has invented not a few building appliances of a practical character. His papers on church planning are well known, and his contributions to the Institute "Proceedings" are on record. The photograph reproduced was taken by the London Stereoscopic Company.

Mr. Henry Currey, F.B.I.B.A., A.M.I.C.E., is a Vice-President of the Royal Institute of British

Architects. The following is a list in brief of his principal buildings:—St. Thomas's Hospital, London; Magdalen Hospital, Streatham; Peninsular and Oriental Co. Offices, London; hotel, London Bridge; hotel and baths, Buxton; Devonshire-park Theatre and Pavilion, the Queen's Hotel and College, as well as the sea wall terraces, &c., at Eastbourne. Mr. Currey erected a mansion in Surrey for Mr. James Wm. Freshfield, and another near Brussels for Mons. Lemmé. He has acted for many years as architect to St. Thomas's Hospital, the Foundling and Magdalen Hospitals. His likeness given herewith is by Mr. Davis, of Eastbourne.

# PRACTICAL ARCHITECTURE WITH DETAILED ESTIMATES.—LXI.

By HENRY LOVEGROVE, F.S.I., Surveyor.

ESTIMATE FOR A VILLAGE ELEMENTARY SCHOOL.

CARPENTER (Continued).

## PRINCIPALS.

ft. in.	ft. in.	
5 24 0	9 8	45 0 Fir-framed tie-beam.
5 2 17 0	6 6	42 6 Add rafter.

1 0		BELL TURRET.
1 0		
6 3	6 3	3 Fir framed in finial.
1	1	Turning to form ball, moulded finial out of 12in. by 12in., and 3ft. 10in. high.
1	1	Turned circular chamfered collar out of 12in. by 12in. by 6, with 6in. diameter perforated and dished at bottom, forming plinth at base of finial.
4 5 0	9 9	
4 5 3 9	9 5	3 9 Fir framed hips.
4 4 6	2 3	Add rafters.
4 5 3 6	2 3	Add for furring.
4 5 2	5 10	Add do.
4 5 2	20 8	Labour circular cutting to 3in.
4 5 2	83 4	Do. to 2in.
2 2 4 2	16 8	23in. deal rounded cir. roll.
8 1	8	Add.
2 6 0	50 0	Circular cutting to end.
4 2	41 4	lin. deal close-jointed boarding, cir. to roof for lead.
8 5 2	41 4	Splay cutting and waste to do.
4 6 0	42 0	Deal moulded cornice with dentil course glued and blocked to design, and 4 C.
4 4 10	19 4	Mitres.
4 1	4	3in. deal carved swelled frieze, 1ft. 4in. wide, tongued both edges and 4 C.
4 5 1	20 4	Mitres.
4 5 1	16 11	4 C.
4 4 7	9 2	Fir-framed head.
4 4 8	7 0	Add below frieze.
4 4 9	4 9	Add below do.
4 5 0	7 6	Add.
4 5 3	7 11	Fir-framed sill.
4 12 6	12 6	Add angle posts.
4 3 8	3 8	Add intermediate.
4 4 7	18 4	Planing to fir and 4 C.
4 4 8	23 4	Add.
4 4 9	19 0	Add.
4 5 0	15 0	Planing to fir.
4 4 6	36 0	Planing to fir and 4 C. angle posts.
4 3 1 5	17 0	Circular ornamental cutting to fir 6in. thick.
8 1 6	12 0	6in. by 23in. fir wrot. and framed uprights.
4 3 8	29 4	Planing to fir and 4 C. intermediate.
4 4 9	30 1	lin. deal wrot. one side cross tongued louvres.

ft. in.	ft. in.	
4 4 9	19 0	Splay and edge to do.
4 2 1 8	13 4	Notching lin., louvres boarding.
3 1 3	5 0	Add.
4 6 9	18 0	Labour groove for lin. louvre boarding cross-grain.
2 2 1 3	5 0	Splayed edge to lin. louvres.
4 2 2 2	1 5	24 7 lin. deal wrot. cross-tongued louvre boarding.
4 2 2 2	1 10	31 9 Do. do.
8 4 1 0	32 0	Labour to groove for lin. and grain.
8 2 1 5	22 8	Add.
8 2 1 10	29 4	
4 4 0	1 9	28 0 4 C.
8 2 2	1 9	30 4 4 C.
8 2 2	2 10	49 1 Add.
5 4	2 3	12 0 lin. deal wrot. cross-tongued framed ventilator.
2 1 4	1 7	
4 11	3 8	Labour raking cutting.
2 1 2	3 8	lin. deal wrot. cross-tongued and framed cover.
2 1 7	3 2	Labour splayed edge to lin.
2 1	1	Labour cutting perforation 9in. by 13in. through lin.
2 1	1	Perforated zinc panel 12in. by 16in.
2 4 8	9 4	Deal wrot. and mitred bead to fix in zinc panel.
4 7	4 7	21 0 lin. deal-jointed boarding and furring for lead.
1 4	1 4	
4 1	4	1 9 Ddt. do.
4 1	4	Labour notching do., 8in. girt.
4 1 8	6 8	Do. 18in. girt.
4 1	4	2in. deal rounded roll.
2 2 4 6	5 3	1 11 Splayed ends.
6 4	4	Fir-framed joists.
6 4	4	Deal moulding out of 3in. by 23in. Mitres.
6 8	4 3	4 C.
1	1	Perforated zinc panel 1ft. 4in. by 1ft. 4in., and fixing to ventilator.
4 10	4 10	23 4 Add.
10	10	8 Ddt. do.
4 2 0	6 4	4 0 Add rolls.
6 0	6 0	3 0 6lb. lead flashing to ventilator.
4 5	1 8	C. C. nailing.
13 4	13 4	1 8 Add.
1 0	13 4	7lb. lead to flat.
4 2 0	16 0	4 Bessed ends to roll.
3 6	2 8	7lb. lead bossed to base of finial.
1 9	3 1	7lb. lead bossed of finial.
4 3 4	60 0	7lb. lead dressed to cir. roof.
4 5 6	14 8	Add rolls.
4 4 8	12 0	
8 1	8	Bessed ends to do.
4 6	24	Soldered dots and screws.
4 6 1	24 4	Deal moulding out of 8in. by 7in.
4 1	4	Mitres.
4 6 1	30 5	4 C.
4 5 3	21 0	Labour to grooves for lead.
4 5 6	106 4	lin. deal close-jointed vertical boarding to base of turret.
2 3 5 6	15 2	Ddt. do.
4 2 6 6	6 13	0 Fir-framed struts.
2 4 3 0	24 0	2in. by 3in. W.I. straps at angles, and 4 C.
8 4 8	21 4	3in. W.I. bolts.
8 4 5 6	32	H.N. and W.
4 5 6	22 0	lin. diameter W.I. bolts and 4 C.
4 4	4	H.N. and W.
2 5 0	10 0	23in. deal rounded roll.
2 4 3 9	30 0	Add.
2 3 3	6 6	Add.
4 1 9	7 0	Add.
2 1 7	3 2	Add.
16	16	M. to roll.
2	2	Splayed ends.
4 5 0	100 0	7lb. lead covering to base of turret.
2 6 9	20 3	6lb. lead apron.
1 6	20 0	Do. flashing.
65 0	43 4	7lb. lead, add for rolls.

ft. in.	ft. in.	
16	16	Mitres of lead roll.
24	24	Soldered dots and screws.
4 4 3	17 0	Deal moulding 3½ in. by 2 in.
4	4	Mitres.
2 20 3		
6		
6	10 2	Fir framed in truss to carving turret.
2 20 3		
9		
6	15 2	Add.
2 5 3 6		
6		
6	8 9	Add uprights.
2 4 6 0		
4		
4	5 4	Add struts.
8 2 0	16 0	2 in. by ½ in. W.I. strap, 4 C.
12 2 0	36 0	Add.

#### THE SOCIETY OF ARCHITECTS.

THE fifth ordinary meeting for the sixth session of this society was held at St. James's Hall, Piccadilly, on Tuesday evening. Mr. F. Clerk Allam, F.R.G.S., vice-president, in the chair. Mr. H. E. Chevallier, of Nice, was elected by acclamation an hon. member, and the following three gentlemen were elected by ballot as members:—William Thorold Lowdell, 9, Great James-street, Bedford-row, W.C.; Denshaw Dorabjee Mistry, 3 and 5, Parsee Punchayet-lane Fort, Bombay; and George Herbert Lonsdale Stephenson, 59, Moorgate-street, E.C.

#### ELECTRICITY IN THE DWELLING.

A paper on this subject, abundantly illustrated by apparatus and also by experiments, was read by Mr. F. Percival Allam. A large assortment of appliances was lent by the Acme Electric Company; Edison and Swan Electric-Lighting Company; Electrical Fittings' Association; Lea, Son, and Company; Wheatley, Kirk, Price, and Goulty; Woodhouse and Rawson; and several others. Mr. Allam described in his opening remarks the chemical battery, and some of the apparatus worked by its aid, including bells, burglar and fire alarms, and then having explained the theory of electromagnetism, and the production of electric currents by induction, he examined the construction of telephones and dynamos. Passing on to his main subject, electricity for lighting, Mr. Allam showed that while for public and street illumination arc lamps were almost exclusively used, their unsteadiness rendered them unsuitable for houses. For the dwelling, however, we have an admirable means of lighting in the incandescent or glow lamps. By means of these little lamps the most artistic effects can be produced—effects which delight the eye, for here we have light without glare. As the heat given off by the lamps is not appreciable, they may be placed close to the walls or decorations of a room if desired. They are indeed under the most perfect control, and by suitably arranging them we can, if we please, have light without any visible source, which is the ideal method in the science of illumination. The brilliancy of the carbon filament can be subdued, if desired, by obscuring the glass globe by roughening its surface by means of the sand-blast, but the more general way is to surround the globes with shades of various shapes and colours. Most of the lamps in use have a nominal candle-power of 16, but in places where a more brilliant light is wanted 32 or 50 candle-power lamps may be used. On staircases and in passages where the light is required but occasionally, eight candle-power are sufficient, and economise the current. It is impossible to give a reliable rule as to the number of lamps required to light any given area, on account of the varying amounts of light absorbed by different coloured surfaces. The only proper method, where practicable, is to take several good oil lamps and place them round the room until the desired effect is obtained. The position of these will then mark where the glow lamps ought to be fixed when the house is being wired. In lighting by gas, to avoid complications of pipes in walls and ceilings, it is the common practice to group the gas jets together as much as possible. It is best, however, to distribute the light as much as possible, and the most pleasant lighting is obtained when the glow lamps are placed round the room about 3ft. from the walls, and from 7ft. to 10ft. from the floor. Nowadays it is unnecessary to speak of the many advantages of the electric light over its rival—gas. One may, however,

mention the lessened danger from fire, the absence of heat, the whiter light, and the freedom from noxious vapours produced by coal gas to the destruction of books and pictures, and harm of animal and vegetable life. When the lamp is to hang from the ceiling the current is brought down the wires which support the lamp and shade; these insulated twin wires are twisted together and covered on the outside with silk to any suitable pattern, and form a pleasing contrast to the inartistic gas-pipe. If the drop be a long one, the line of straight wire is generally relieved in the middle by glass beads or ornamental metal sprays threaded on. When brackets are used, care should be taken to avoid making them look like adapted gas-brackets. Artistic forms in wrought iron and hammered brass and copper are readily designed for the purpose, so as to harmonise with the style of decoration and furnishing of the room. When a house has its own generating plant, the engine and dynamo are usually placed in the basement, or in a separate building outside. The cable is brought from thence to a switch-board, on which is placed a main switch for breaking the whole current if required, an ammeter and voltmeter for measuring the current, and an automatic cut-out for breaking the circuit, should there be an excessive flow of current through any accidental cause, such as two naked wires coming accidentally into contact. From this board wires branch off to the various rooms. When houses in course of construction are wired for the light, the wood casing containing the cable and wire is fixed to the naked brick walls, and hidden from sight by the subsequent coatings of plaster. This makes very neat work, and if the house is a fairly dry one, the buried wires, well insulated with pure indiarubber, and the work properly done, there is little likelihood of anything going wrong. At present, however, the task usually presented to the electrical engineer is to run the wires in a house, not only finished and decorated, but furnished. Then the casing has of necessity to be fixed to the wall, and is apt, if care is not taken, to spoil the decoration and appearance of the room, besides producing the usual damage in cutting away for inserting the wooden plugs. In order to minimise this disfigurement as much as possible, Messrs. Nicholson and Jennings have recently introduced a new kind of casing made of a material resembling Lincrusta Walton. This material can be moulded to any design, and coloured to suit the intended surroundings, while the cost is not more than the ordinary wood casing. When the wires have to run across the ceiling this might be used with advantage, dummy lengths being run at right angles to form panels. Split bamboo canes have been lately suggested for use in covering the wires. These would look extremely well, if polished, and would match the Japanese furniture and decorations now found in so many houses. A better plan, however, than running the casing on the ceiling, is to lay it under the floor of the room above, across the joists, bringing the wires down through the ceiling. In most cases wires from the lamps are brought down the walls to switches; these control the current for any given lamp or lamps, and take the place of the gas tap. Sometimes, however, the switch is placed in the holder, just above the lamp. The switches are generally made with a slate or china base, with a metal, wood, or china cover. The arrangement of the mechanism inside varies with every maker; but the object is in each case the same, to break and close the circuit by the movement of a handle or lever, care being taken that good contact is made between the metal parts conveying the current when the switch is "on," and that there is a good spring keeping the switch always "off" until moved by hand into the reverse position. A "wall socket" is a handy arrangement for obtaining a light that may be shifted to different parts of a room. At any convenient point on the wall a socket is fixed, to which the wires from the mains are led. When a light is required in the movable lamp, all that has to be done is to connect it with the socket by means of a flexible wire cord, with a plug at one end. By having several of these sockets placed in various parts of the room, the electric lamp may be made as portable as the common oil table-lamp. The householder, on the introduction of the electric light, is apt to imagine that, having got rid of his gas-pipes, he need no longer dread the possibility of fire. However, when one considers the intense heat generated in the electric arc, and the fact that the glowing of the fila-

ment in incandescent lamps is also the result of heat, it is obvious that the element we have to deal with is by no means of an inoffensive and harmless nature, and that immunity from fire can only be obtained by adhering to the required conditions, by exercising great care in the perfect insulation and protection of the conductors. Much of the care displayed in England by the electrical engineer has been due to the stringent rules drawn up by the Fire Offices, and which have to be strictly adhered to by the contractor in order that the work may be passed by the company's inspector. The rules published by the Phoenix Fire Office, under the direction of Mr. Musgrave Heaphy, are those most generally used. These rules deal with the details that have to be observed by the contractor, such as the proper insulation of the wires and cables, the distance at which the wires must be laid from one another, and the introduction of a proper number of fuses in the circuit. Some of these rules may appear unnecessary and to show over-carefulness, but it is better to lean to the side of over-carefulness, and these rules have greatly increased the adoption of the electric light by inspiring the public mind with confidence in its perfect safety as well as its many other advantages, for, by adhering to these rules, electric lighting may beyond doubt be made absolutely safe. The Phoenix Fire Office, in the preface to its rules, remarks, "The electric light is the safest of all illuminants, and is preferable to any others, when the installation has been thoroughly well put up." The author concluded by giving a short description of the various systems now in practical use for the distribution of electricity from central stations. The first and oldest method is, he remarked, to employ continuous currents at a low pressure. This can only be done when the supply station has its customers all within a small radius, for as the cross-sectional area of the main cable has to be increased in proportion to the current, a very large amount of copper has to be used when the current is great, thus making the cost of the mains a very heavy item when the district served is a large and straggling one. To avoid the use of these expensive mains, a new system has been brought into use during the last few years, and has been almost universally adopted where the lights are scattered over a large area. This is known as the "transformer system." The dynamos employed are designed to give currents of a very small quantity but of high pressure. They, moreover, instead of being continuous, as in the low-pressure system, alternate very quickly in their direction. The currents thus generated do not flow through the lamps, but through a piece of apparatus called a "transformer," which is placed in the dwelling to be lighted. This transformer works on the principle of the medical induction coil. The high-pressure current traverses a number of coils of fine wire. Over these coils are wound a smaller number of turns of coarser wire, the ends of which are connected to the lamps. Owing to the current in the fine coil alternating, varying lines of magnetic force are formed, which cut the coarse coil, producing alternating currents in the lamp circuit. This "secondary" current, however, is of a large quantity and at a low pressure. The main cables used in this system are of small size, and can be laid down at a moderate cost; but great care has to be taken that the insulation is kept perfect, otherwise great loss is sustained by the current leaking to the earth, and there is the risk of workmen who may accidentally touch the defective cable receiving dangerous shocks. The third method to be mentioned is also on the converter principle, in which a small high-pressure current is transformed into a low-pressure current of greater quantity. In each house or sub-station a battery of accumulators is placed, and the high-tension continuous current from the central station has to pass through each set of the batteries in any given district. The secondary current from each sub-station is taken from its own battery. Thus, if there are ten sub-stations and batteries in any district, the pressure on each secondary circuit will be but one-tenth of the pressure of the current supplied from the central station. As the authorities have forbidden electric-light wires to be run overhead, every company has now to lay its mains underground. Several systems are in use, the chief aim being in each case to keep the two cables well insulated from each other and from the earth, and protected from accidental blows of picks and shovels. Some-

times the cables are well insulated with india-rubber, sheathed with lead, and then placed in earthenware or wooden pipes filled with creosote and pitch. Another plan is to place the naked copper in brick conduits or iron troughs, simply insulating it by running it on earthenware or porcelain insulators.

A short discussion followed, in which Messrs. E. Tidman, W. Allport, C. E. Gritton, and Alfred Howard took part; and a vote of thanks was passed to the lecturer.

#### STUDENTS' PRELIMINARY EXAMINATION AT THE INSTITUTION OF SURVEYORS.

OF the candidates who presented themselves at the Preliminary Examination of the Institution of Surveyors, held concurrently in London and Manchester on the 21st and 22nd inst., the following satisfied the examiners:—

Edwin Crossley Atkinson, Hill House, Thurlow, Suffolk; Guy Berry, Burton House, Wandsworth Common, S.W.; John Friendship Bowden, 33, Haldon-road, St. David's, Exeter; Harry Greaves Bradshaw, 26, Demesne-road, Withington, near Manchester; Thomas Edmund Carr, Moor Monckton Rectory, York; Lionel Cooke, 20, New Bridge-street, E.C.; John Hunter Cranston, Swains-hill, near Hereford; Robert Gerald Craske (passed at head of list), Beverley-road, Colchester, Essex; Frederick Kersey Debenham, Heath House, Commercial-road, Stepney, E.; Martin Collier Duchesne, 2, Faircroft-terrace, Audley-road, Saffron Walden; Walter Robinson Elgar, Crockshard, Wingham, Kent; Gilliebrand Elwin Evered, The Firs, Clarence-road, Clapham Park, S.W.; Arthur Sherman Everett, Berry, Totnes, Devon; Fred Finn, 2, Serpentine-road, Sevenoaks, Kent; Herbert Phillips Fletcher, Anglebay, Woodchurch-road, West Hampstead, N.W.; John Sainsbury Gilbert, Granville, Mill-hill Park, Acton, W.; Frederick Algernon Green, Merevale, Bickley Park, Kent; Francis Henry Hankinson, Eastbury, Bournemouth, Hants; Ernest Wivelsfield Harrison, Bugbrooke Rectory, Weeden, Northamptonshire; Percy Cave Holiday, Bicester, Oxon; Frank Wilnot Jarman, 4, High-street, Croydon; Barnard Marr Johnson, 3, Sussex-square, W.; Walter Nike King, Westcroft, Tring, Herts; Alfred Millington Knowles, Colston Bassett, Bingham, Notts; John Herbert Margetts, Ashberry House, Warwick; Walter North Martyn, Tower House, Poole, Dorsetshire; James Frederick Mellor, 100, St. James's-street, Brighton; John Pettitt Ogilvie, Elmswood, Marlborough, Wilts; Peter Arnold Ouvry, East Acton, London, W.; Leonard Ronald Preston, 26, Fellows-road, South Hampstead, N.W.; Charles Bates Purnard, Underley Estate Office, Kirkby Lonsdale; Herbert William Raffety, Fairholme, High Wycombe, Bucks; Thomas Scott, West Ham Vicarage, London, E.; Ernest Soutter, The Paddocks, Guildford; Ernest Allen Stapledon, Royal Agricultural College, Cirencester; Benjamin Henry Symons, Bridge Town, Totnes, Devon; Frederick Wilson Temple, 27, Sandgate-road, Folkestone, Kent; John Homan Thorpe, 10, Market-square, Bromley, Kent; Francis William Walker, Plas Grove, Hooton, Cheshire; Francis John Walkington, Greythorne, Kingstons, Ireland; William Henry Wells, 14, Girdler's-road, West Kensington, W.; Ernest Victor Whitaker, Wandsworth Lodge, Upper Tooting, Surrey; Frederick Yeo, Okehampton, Devon; Thomas John Young, Breckon-hill, Hexham, Northumberland.

#### CHIPS.

St. Peter's Church, Worcester, was reopened on Friday after restoration. The works, which have cost about £1,300, have been carried out from the designs and under the personal superintendence of Messrs. Yeates and Jones, A.R.I.B.A., architects, Angel-place, by Mr. John Bourne, contractor. Mr. Taylor, of Birmingham, did the decorations, and Mr. W. Forsyth, Tything, the pulpit and wood carvings. Mr. W. Birbeck, Ledbury, the hot water apparatus, the Worcester Gas Company the gas pipes and fittings. The altar rail, lectern, and other brass work, &c., were provided by Messrs. Jones and Willis, Birmingham. The encaustic and geometric tiles were provided by Messrs. W. Godwin and Son, Hereford.

A Liberal club and hall are to be built at Bedminster, Bristol, from plans by Mr. F. W. Willis. Mr. A. J. Beaven, also of Bristol, is the builder, and the cost will be about £5,000.

A new Constitutional Club has been erected at Oxford, and special attention has been paid to the ventilation which is carried out on the Boyle system.

A new free library is about to be built at Kidderminster, harmonising with the adjoining schools of science and art. Mr. J. M. Meredith, of Kidderminster, is the architect.

The town council of Middlesbrough have under consideration a recommendation from a committee proposing that an eminent engineer be called in to advise as to the desirability, cost, and method of constructing a bridge across the Tees from Middlesbrough to Port Clarence.

A chapel is being added to the workhouse at Droitwich for the board of guardians. Mr. W. Small is the contractor, and a stained-glass window is to be put in the building. Messrs. Jones and Willis, of London and Birmingham, being the artists.

## Building Intelligence.

**LONDON COUNTY COUNCIL.**—At Tuesday's meeting of the Council it was decided by 42 votes to 38 to instruct a committee to report as to the acquiring of a suitable site for a council chamber and offices. A committee reported that the alterations at Spring-gardens had now sufficiently advanced to render it desirable that steps should be taken for arranging the seating of the council chamber, and for obtaining the necessary furniture. It was decided to invite tenders for the work from selected firms. The chairman of the committee *re* Brass and Sons, reported that the committee had very carefully considered the reference to them by the Council, directing them to investigate and report upon the accusations affecting the position and standing of Messrs. Brass and Sons, and reported that, in view of the present state of the law and of the many legal difficulties that would attend the procedure under the reference, they were unanimously of the opinion that it was not desirable to carry on the inquiry. They accordingly recommended "that the reference be discharged," and this was agreed to. On the motion of Sir J. Lubbock, it was determined that the officials of the Council should be instructed to watch for and collect any objects of antiquity which might be met with in excavations carried on by the Council with a view to the preservation of such objects, either in a special municipal collection, or in the British Museum, or in the Guildhall Museum, as the Council might determine.

**MEXBOROUGH, ROTHERHAM.**—A new board school, situate on the common, was opened last week. The building has been constructed from plans prepared by Mr. Tacon, of Rotherham, the architect to the board, the work being undertaken by Mr. G. H. Smith, builder, Mexborough. The total cost will be about £2,000. The character of the structure is plain Tudor Gothic. Accommodation is provided for a mixed school of 102 children, in addition to four class-rooms, two for 60 each, and two for 50 each. There is a separate entrance for boys and girls; lavatory, cloak-room accommodation, and the necessary outside conveniences. The ventilation of each room is by the appliances of Robert Boyle and Co., Limited, and the heating is by means of hot-air stoves by Messrs. Wright Bros., of Sheffield. The children have separate playgrounds. The building is of rock-faced stone from local quarries, the brick also being from Mexborough kilns.

**NEWCASTLE - ON - TYNE.**—New lithographic printing premises have just been built in Clavering-place for Messrs. R. Robinson and Co., on the site of others destroyed by fire. The new works occupy practically the same position as those burned down, but the planning and construction are entirely different. More floors have been added, each floor being of a greater height than before. The building, which was erected on new foundations, is solidly constructed in brickwork, and lined throughout with white glazed bricks. The floors are supported from basement to roof by iron columns; upon these rest steel girders, which, in turn, carry the floors. The staircase is built entirely of incombustible materials—stone, brick, and iron. There are six floors in height, containing an aggregate of 30,000 superficial feet. The whole of the buildings are warmed by a hot-water apparatus. A lift adjoins the staircase, and extends from the basement to the top floor. This lift is driven by the "Otto" gas-engine. The buildings were designed and carried out under the superintendence of Mr. Frank W. Rich, of Newcastle.

Colonel Rich, inspector of railways, on Thursday inspected the new railway constructed from Chester to the Dee Bridge by the Manchester, Sheffield, and Lincolnshire Railway Company. The line is seven miles in length, and at the bridge joins the Hawarden Loop Railway now in course of construction. Among those present to receive the inspector were Mr. Fox, engineer; Mr. Cotterill, resident engineer; and Mr. Logan, contractor.

Mr. A. F. Fowler, C.E., engineer to the Tees Conservancy, the York Corporation, the Aire and Calder Navigation, and the Whitby Harbour Trustees, has been recommended by the Ribbles Committee of the Preston Corporation to be appointed by the Town Council, at their next meeting, the resident engineer of the Ribble improvement works at the estuary of the river, at a salary of £500 a year.

#### ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

**EDINBURGH ARCHITECTURAL ASSOCIATION.**—A lecture on "Symbolism" was given by the Rev. Edward Sugden, of Dundee, to the members of the Edinburgh Architectural Association on the 23rd inst. Professor G. Baldwin Brown, president, was in the chair. The lecturer defined "symbolism" as that which treats of the representation of the real by the ideal. He pointed out that some of the chief things used in symbolism were letters, figures (geometrical and others), flowers, stones, colours, costumes, acts, sounds, numbers, names, and animals. He showed that letters are symbolical of man's thoughts; that figures, combined with colours and acts, gave us a great diversity of signs; and that flowers may symbolise a solemn, religious doctrine, or the tender passion of a young man for his ladylove. He also directed notice to costumes, ecclesiastical and civil, and gave the beautiful symbolism of the various instruments that may be introduced into the sunrise portion of Haydn's "Creation." Reference was made, in closing, to the symbolism of heraldry and shop signs.

**ST. PAUL'S ECCLESIOLOGICAL SOCIETY.**—The eleventh annual report, 1889-90, of the council of this Society, to be read at the annual meeting to-morrow (Saturday) afternoon at St. Paul's Chapter House, states that the proceedings of the past year have been very satisfactory; the papers read at the evening meetings have been of great interest, and the visits, with one exception, have been very largely attended. During the year ten meetings have been held in the Chapter House, and papers have been read by Mr. A. Oliver, the Rev. Ernest Geldart, the Rev. E. S. Dewick, Mr. G. H. Birch, the Rev. H. Hamilton Kelly, Dr. J. Wickham Legg, and Mr. F. Hamilton Jackson, and on one evening members were invited to bring for exhibition, and to describe, objects of ecclesiastical interest. This was a new departure, but the result was so successful as to warrant a repetition of the experiment in the future. Afternoon visits were made to the churches of St. Mary Abbot's, Kensington, St. Cuthbert, Kensington, and Hammersmith; to All Saints, Fulham; to Chiswick Parish Church, to St. Alban's Cathedral, to Bow and Stepney, to Winton, and to Aveley. Twenty-two new members have been elected during the year; the number on the register is now 274.

**THE ART OF GLASS STAINING.**—A meeting of the Architectural Section of the Philosophical Society of Glasgow was held on the 23rd inst., Mr. T. L. Watson, F.R.I.B.A., vice-president, in the chair. Mr. Stephen Adam, glass stainer, read a paper on "The Progress in the Art of Glass Staining." He regretted that cheap shoddy work was now so much in request, and pointed out the blasting effect it would have on the glass-staining art. It was common to see the terms "Artists in Stained Glass" standing over glaziers' and window-cleaners' shops. If the art of glass-staining was to run in such channels it would tend to degrade, as it was doing, an ancient, honourable, and beautiful craft. He traced the development of the art down to modern times, and pointed out the characteristics of the various periods. Referring to some recent stained-glass work, Mr. Adam said he could not enter the noble cathedral of Glasgow without experiencing a keen sense of pain. The feeling was overpowering that these painted windows were never meant for the position they occupied. The scheme of colour was offensive, the regular massing of glaring, primitive colours, and the absence of second and tertiary colours was against all rule, and did not appeal to cultivated taste. Take away the sacred texts, and they might well transfer the most of these windows to a music-hall or other place of entertainment. In addition to all that, the windows were fading. In Paisley Abbey they had stained glass, good and bad, thrown, as it were, recklessly into the window openings. There was a scheme of stained glass in Glasgow Cathedral, but in Paisley Abbey there was no intelligent arrangement.

At a vestry meeting held at St. Edmund's Church, Exeter, last week, a report by Mr. F. J. Commis, of that city, recommending the erection of a new wooden ceiling and roof, was adopted. The church has been closed for some time, owing to the fall of a portion of the ceiling and the threatening appearance of other parts.

## TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

## TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.). To India (via Brindisi), £1 10s. 4d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

## ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

## SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING for TWENTY-FOUR WORDS, and SIXPENCE for every eight words after. All Situation Advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page advertisements and alterations in serial advertisements must reach the office by Tuesday Morning to secure insertion.

## NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XLII., XLVI., XLIX., L., LI., LIII., and LVI., may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—C. N. and Son.—A. and H. M.—W. G. and Son.—A. C.—E. G. M.

OLD T-SQUARE. (There is no use in publishing your letter. We have submitted it to the author, and he declines to continue the controversy—we suppose, because he has had enough of it.)

## "BUILDING NEWS" DESIGNING CLUB.

## FOURTH LIST OF SUBJECTS.

Subject E.—A Cabman's Shelter and Newspaper Kiosk with Illuminated Clock Tower between. This building is for a site in the middle of a main thoroughfare of a large town adjoining a cabstand, and situated on a paved island or street refuge, 43ft. long by 13ft. wide. At one end of this site, in front of the kiosk, the paving is to be rounded, and the other end left square, next cabstand, the building being so placed on the island as to allow ample space for foot-passengers in front of the paper-kiosk. The shelter, which is to be of timber, filled in with panelling or V-jointed boarding, is to measure inside 20ft. long by 8ft. wide. Out of this a little kitchen place, 6ft. by 8ft., is to be formed, with a glazed screen dividing it off from the main part. The two entrance doors (2ft. wide, made sliding) are to be situated, one on either side, between the kitchen and the main refreshment place. A seat, 1ft. 6in. wide, is range along the sides, but not at the end, and the table is to be in the centre. A small American cooking stove is to be placed in the kitchen, with flue in tower wall, and a sink with plate-rack and cupboard for cups, &c. The shelter is to stand on a brick, or stone, plinth, 14in. high above pavement, and the floor is to be finished in cement on concrete. Provision for a dust-box outside to be made. Roof covered with red tiles. Ventilation to be provided for. The clock tower, 30ft. total height to final, is to be of brick or stone, 9ft. square outside, on plan at base; upper part may be of timber, like the roof, which is to be covered with lead. Clock faces on all four sides. The kiosk for sale of newspapers is to be of timber, like the shelter, and to project from the other side of the tower, 4ft. 6in. inside by 6ft. wide, and rounded on plan to follow line of pavement. The base of the tower is to be open into kiosk, to be used by the vendor of papers, and his doorway into the kiosk to be in one of the flank external sides of the tower. Plan, 3 elevations and section; scale, 4ft. to the inch. Sketch and small-block plan showing position on island. Style optional.

DRAWINGS RECEIVED.—"A. G." in a circle, "Herbert," "Sarchedon," "Labor Omnia Vincit," "Nightlight," "Airedale," "Streona," "Cassowary," "North Star," "K. W. T.," "Fleur de Lis," "Pat," "Niger," "Glaucus," "Nox," "Niblick," "Lycidas," "Bunya," "Dot," "Pat," "Do-no," "Koko," "Waverley," "West Anglian," "Menelaus," "Coaly Tyne," "St. Magnus," "Jeky," "McGinty," "Tyne," "Westward-ho," "So and So," "Jehu," "Coverac," "Reference."

## Correspondence.

## CLERK OF WORKS AND WHOLESALE CONTRACTS.

To the Editor of the BUILDING NEWS.

SIR,—Will you allow one who, in twenty-five years' responsible charge of contracts, has had both systems to deal with, to express a different opinion to that in your article on above? My own experience is that the smaller the contractors the greater the scamping, and that separate contracts means keeping some half-dozen tradesmen all eager to make a profit out of one piece of work rather than one, and instead of six tradesmen anxious to do good work, the unfortunate architect and clerk of works finds himself faced by six tradesmen, each keenly anxious to make as much money out of the work as possible. The rows and bothers there are to settle where one trade's obligations ends and the other begins will give as much trouble as the rest of the work, and one scamping tradesman will set all the others by the ears.

Your shocking example, the London School Board, is an unfortunate one, as these schools were nearly all subtle to separate contractors by one contractor, and the system of open tendering and monthly payments directly helped men to undertake work of this kind beyond their capital or experience.

It is notorious that some of these contractors had no workshops, and scarcely a yard, when they took contracts, and that all their work was sublet, except, perhaps, the material of brick-layer and carpenter.

I do not know the superior officer of the board or his experience; but I venture to say that if such a superior officer visited all the buildings in London erected under open competition he would find 75 per cent. with as gross scandals as the Board schools, and if he visited the North and West of England, where separate tenders are the rule, he would find 80 per cent.

Architects have the matter in their own hands. Write a careful specification—do not leave the office boy to do it with the scissors—choose a competent and trustworthy clerk of works, and see he does his duty, and stand by him; keep a high standard, and scamping builders will shun the office.—I am, &c.,

ROBERT PHILLIPS.

SIR,—I have read with interest your article last week on "Wholesale Contracts." As regards your suggestion to obtain "separate contracts" for a building, the idea is very good; but from experience I have found the trades clash one with the other—the bricklayers with carpenters, and *vice versa*, and so it goes all through; whereas under the old style, where a general foreman looks after things, one trade works into the hands of the other, and the work proceeds more pleasantly to all parties concerned.

I take it the reason why jerry-work creeps into buildings, even where a clerk of works is employed, is that some architects do not give their clerk of works the full power the latter ought to be in possession of. You state that under your proposed order of tendering "the clerk of works would be more a master of the situation than he is now." If he is not at the present time fully master of the situation, whose fault is it but the architect's?—who, instead of looking upon him as his representative, and placing full power in his hands, together with all information even of a financial nature relative to the building, and insisting that no communication either to or from the builder should pass otherwise than through his hands, seems to put him on one side in some cases, and only allows him a quarter the power he ought to have. As a natural consequence, the builders, who are, as a rule, men of keen perception, take the advantage; whereas if the clerks of works were always treated as they ought to be, I am sure better buildings would be the result, and greater satisfaction be given both to architect and client; he would then be fully master of his position, and whenever the builder through having the contract too low began to be "dictatorial," he would find that of no use. In time, likewise, I am confident, were this to be general, a difference would soon be seen in the builders' tenders, who, if they knew they had but little chance of scamping, would not cut their prices down so low as at present.—I am, &c.,

BUFF TERRACOTTA.

## Intercommunication.

## QUESTIONS.

[10214].—**Earthwork Slopes.**—Can any of your readers tell me of a book that gives information as to the proper slopes to cuttings, embankments, open water-courses, and ponds?—J. S.

[10215].—**Wood-Block Floor.**—Seven years ago I had a floor laid with 8in. by 4in. by 1in. wood blocks on a 6in. bed of ground-lime concrete, with a 1in. thick Portland cement-floated bed on top of concrete. The blocks were laid in cement before the floated bed was thoroughly set. The floor has proved a complete failure, and on examination it is found that the underside of blocks have become quite rotten, and not fastened by the cement whatever, but quite free. The floated cement bed is very dry and hard. Over where hot-water pipes are embedded in the concrete the blocks seem more rotten than elsewhere. What is the best to do with it? and will the composition used by wood-block floor layers generally prevent this decaying process? and of what is their composition made besides pitch and tar?—SAWSET.

[10216].—**Ageing Pitchpine.**—Will any of your readers kindly say what kind of chemicals would be suitable for giving pitchpine an aged and mellow appearance, similar to that seen upon pitchpine framing after being exposed for a long time before varnishing? It assumes a deep purple.—BUILDER.

[10217].—**Architect, Client, Builder.**—1. An architect gives a certificate in favour of a builder, and his client refuses to honour it. What position does the builder stand in? 2. If an architect sends a final certificate to his client, and not the builder, who has been the recipient of all former certificates, and the client wishes his architect to reduce the amount of the certificate, and he does so, can the builder, who is in a position to prove the certificate being written for the larger amount, sue his client for the same?—H. H. T.

[10218].—**R.I.B.A. Exam.**—Is it absolutely necessary to prepare all probationary drawings on half-sheets of double-elephant paper, 27in. by 29in.? I have carefully prepared some drawings on paper 22in. by 15in. Would these be accepted? Will Mr. Middleton, or "G. H. G.," oblige?—H. H. T.

[10219].—**Damp.**—Would you permit me to ask the assistance of your readers in my dilemma? I had a house built 13 years ago, and cannot keep the N.E. walls dry. The damp shows only in a moist (not necessarily rainy) atmosphere. I tried a solution guaranteed to cure all damp walls. It did no good. A couple of coats of good paint were then tried—no better. I then built a room on, making it an inner wall; still no better. Can any of your courteous readers suggest a cure? I may say it does not arise from the damp-course, as it is only the upper portion of the wall which is affected.—PAILO.

## REPLIES.

[10204].—**Crushing Weight of Stone.**—Tests of picked specimens are very deceiving. Dry Bath stone between pieces of pine behaves in a different manner to what we find in practice. Practically we find stock bricks will carry 5 tons per square foot; Bath stone and Ancaster, 10 tons; hard laminated sandstone, 30 tons; blue brick, 20 tons.—ROBERT PHILLIPS, County Surveyor's Office, Gloucester.

[10206].—**Strains.**—From the formula  $\frac{c b d^2}{L} = W$  it can be shown that  $d^2 = \frac{W L}{c b}$ . The strongest section for a rectangular beam is when the depth and breadth are as 7 to 5—that is, breadth ( $b$ ) =  $\frac{5}{7}$  depth ( $d$ ). Substitute  $\frac{5}{7} d$  for  $b$  in the above. Then  $d^2 = \frac{W L}{c \frac{5}{7} d}$ . Therefore,  $d^3 = \frac{W L}{c} \times \frac{7}{5}$ . Hurst's constant for northern pine = 4, and factor of safety = 5. Then  $d^3 = \frac{15 \times 20 \times 7 \times 5}{4 \times 5} = 525$ ; then  $d = \sqrt[3]{525} = 8$ , and  $b = \frac{5}{7}$  of 8 = 5 $\frac{1}{2}$ . Therefore the section of the beam should be 8in. by 5 $\frac{1}{2}$ in.—H. CARTER PEGG.

[10206].—**Strains.**—As "Como" will perhaps prefer the "strains" worked out according to the formula he gives, I send the following:—As the beam must not be loaded more than one-fifth its breaking weight, we must take the weight  $15cwt \times 5 = 75cwt$ . We then have  $75 = C \frac{b d^2}{20}$ , and taking  $C$  at 4 for fir timber,  $75 = 4 \frac{b d^2}{20} = \frac{b d^2}{5}$ , or  $b d^2 = 375$ .

Now let "Como" decide upon a depth of beam suitable to the span, say 10in. Then  $b \times 10 \times 10 = 375$ , and  $b = 3\frac{3}{4}$ . In the reply given last week the beam is taken as loaded to one-sixth the breaking weight.—J. W.

[10206].—**Strains.**—The formula for weight which your correspondent "Como" gives can easily be employed for finding the dimensions of the timber beam, if the value of the constant  $C$  for the particular kind of timber to be used be known. For, evidently:

$$b d^2 = \frac{W}{C} \times \frac{L}{l} \times \frac{1}{b}$$

$$\text{Therefore: } b = \frac{W}{C} \times \frac{L}{d^2} \times \frac{1}{b} \quad \text{or} \quad d = \sqrt{\frac{W}{C} \times \frac{L}{b}}$$

Suppose  $b d^2 = 12$ , then since  $2 \times 6$  or  $3 \times 4 = 12$ , either of these numbers may be taken. That being chosen which would be most convenient, we have only to extract the square root of one of them, and we have the two dimensions of a beam with length of bearing =  $l$ , which will bear the strains produced by a weight =  $W$ .—J. EAUZ.

[10203.]—**Strains.**—In reply to "Como," the following is method of working out the formulae:—

$$\begin{aligned} 15\text{cwt.} &= \text{weight} \\ 5 &= \text{factor of safety} \\ 75\text{cwt.} &= \text{breaking weight} \\ 3.6 &= \text{C. for fir} \\ 3.6 \frac{b^2}{20} &= 75 \end{aligned}$$

this gives  $b^2 = 417$  nearly  
 $b$  should be  $\frac{20}{7}$  of  $d$

$$\text{Let } c = d, \text{ then } \frac{5c}{7} = b$$

$$\text{then } \frac{5c}{7} \times 2 = 417$$

$$d \text{ or } c = 8\frac{1}{2}\text{in. nearly}$$

$$b \text{ or } \frac{5c}{7} = 6\frac{1}{2}\text{in. nearly.}$$

—J. E. M.

[10206.]—**Strains.**—"Como" very naturally finds some difficulty in obtaining the values of two unknown quantities from one equation in which both occur. The difficulty may be evaded by assuming a value for one of them; in practice it is easy to settle for which—e.g., in the case of a beam spanning an opening in a wall,  $b$  is fixed by the width of the wall, and in case of a beam supporting a floor, though the economy of material increases with the increase of  $\frac{b}{d}$ , yet as increasing  $d$  would

increase the gross height of the building, the economy in timber would be partially or wholly balanced by the extra brickwork required, so that the ruling factor will probably be the market size of timber. Taking the ordinary formula for beam supported at both ends, weight in centre, constant for yellow pine (Molesworth, Ed. 21, p. 122). "Como's" problem works out as follows:—

$$W = \frac{4 \cdot k \cdot b \cdot d^2}{7} \quad \text{Safe load} = \frac{W}{5}$$

$$\therefore \text{Safe load} = \frac{4 \cdot k \cdot b \cdot d^2}{35}$$

$$\therefore 15 = \frac{4 \cdot 10 \cdot b \cdot d^2}{35}$$

$$\therefore b \cdot d^2 = 450$$

$$\text{say, } d = 9\text{in., then } b = \frac{450}{81} \text{ or } 5\frac{1}{2}\text{in. nearly}$$

$$\text{" } 11\text{in. " } \frac{450}{121} \text{ or } 4\text{in. nearly.}$$

—L. G.

### CHIPS.

At a special meeting of the Sale Local Board, held recently, the surveyor (Mr. A. G. McBeath) submitted details of a scheme for the disposal of the sewage of the Board's district. The system to be adopted is known as the international process, and the effluent can be turned into the river Mersey. The scheme will deal with 2,220,000 gallons of sewage per day, and pumping machinery will be constructed to deal with eight millions per day. The site of the works is a little over  $\frac{1}{2}$  acres, and the cost of impounding tanks, filter beds, and pumping apparatus is estimated at £14,733. The plans have been conditionally approved.

The memorial-stones of a new Sunday-school for the New Connexion Methodists of Ardsley, near Barnsley, were laid last week. The present school accommodates about 160 scholars; the new one will accommodate 300, and the old school will be converted into three class-rooms. The cost will be about £800. Mr. J. P. Kaye, of Leeds, is the architect, and Mr. Thackeray, of Leeds, the contractor.

At the annual meeting of the Edinburgh Association of Science and Arts, held on Monday, Mr. Alexander Donald Mackenzie was appointed president, Mr. Alexander Lawson and Mr. George James Beattie vice-presidents, Mr. R. M. Westwater secretary, and Mr. John Turpie treasurer for the ensuing year. The retiring president (Mr. Turnbull) addressed the meeting, and Mr. James Macdonald read a paper on "Lead and its Application to Building Construction."

The new Assembly Rooms at Whalley, near Blackburn, have just been opened; they comprise a large hall, stage, retiring-rooms, smoke-room, caretaker's house, and storage, and have cost, including furnishing, about £2,300. Mr. C. Sydney Ingham, of Manchester and Southport, and Mr. M. Wilkinson, of Blackburn, have acted as joint architects, and the work has been carried out by local contractors.

Messrs. Sugden and Son, of Leek, the architects employed to adapt the Mechanics' Hall, Hanley, for the purposes of a Technical Museum for North Staffordshire, which is expected to be of a permanent character, have made a further report to the Hanley Corporation as to the unsafe condition of the building and the expensive works necessary to render the building safe. This was discussed at length by the town council at their last meeting, it being pointed out that the building was allowed to become dilapidated before the Corporation came into possession of it. The report was eventually adopted.

At a meeting of the congregation of St. Paul's Established Church, Greenock, held on Friday, it was unanimously agreed to erect a new church on the site of the present building at a cost of about £8,000. The new church is to seat about 700 people.

### LEGAL INTELLIGENCE.

**IN RE C. J. BURSILL.**—Mr. Registrar Giffard made last week a receiving order under a petition presented by the debtor, a builder and contractor, of Iverson-road, Kilburn, and West Hampstead. The liabilities are given at £29,500, of which £25,000 are secured.

**IN RE WAWMAN.**—(London Bankruptcy Court, January 20, before Mr. Registrar Linklater.)—The bankrupt, a builder at Felixstowe, in Suffolk, formerly carrying on business at Croydon, applied for an order of discharge. The failure occurred in October, 1885, the liabilities being returned in the statement of affairs at £7,200, and there were no assets. The Official Receiver reported in opposition that in 1880 the bankrupt filed a previous petition, under which the creditors agreed to accept a composition of 8s. in the pound, which was never paid. The trustee made six other specific charges against the bankrupt. Mr. Registrar Linklater now gave judgment to the effect that all the charges made against the bankrupt except one failed, and that he had only to consider the case with reference to the offence found in the Official Receiver's report—viz., the previous failure in 1880. Being of opinion that the offence of the previous failure was surrounded by circumstances of great aggravation, he should suspend the order of discharge for three years from this date.

**DANGEROUS PARTY WALLS AND THE BUILDING ACTS.**—**CHARLES V. GOVER.**—(Jan. 21 and 22, Chancery Division, before Mr. Justice Kay.)—The plaintiff and defendant are owners respectively of Nos. 69 and 68, Basinghall-street. The defendant having pulled down his house, No. 68, with a view to rebuilding, proceeded to underpin the party wall, which was a very old one standing upon elm boards and cross timbers, which rested upon mud, and it was alleged that the defendant left the wall in a dangerous condition. In March, 1888, the plaintiff and defendant were served by the Commissioners of Sewers with a dangerous-party-structure notice under the Metropolitan Building Acts. In spite of the notice and a complaint by the plaintiff the defendant continued the work and erected a wall tied to the plaintiff's wall and built on it in such a way, it was alleged, as interfered with ancient lights in the plaintiff's house, which is used for office and warehouse purposes. The plaintiff then brought the present action for an injunction to prevent the defendant allowing the party wall to remain in its dangerous condition, also to restrain the defendant from interfering with the ancient lights, and for damages. The plaintiff obtained on motion an interim injunction restraining the defendant from doing any of the works mentioned in section 83 of the Metropolitan Building Act, 1885, except such as were required to be done by the dangerous-party-structure notice. As the defendant continued his work in spite of the injunction he was served with notice to commit him for breach of the injunction. This motion came on with the trial of the action, which was heard on Tuesday and Wednesday week. Mr. Justice Kay said the case was not a satisfactory one, because it seemed to him that in this Metropolitan architects and contractors went to work as if there were no such Acts as the Metropolitan Building Acts in existence, and did not take the slightest pains to act in accordance with them. He had been entertained by an argument that, notwithstanding the injunction and the notice, the defendant was at liberty to build anything he liked. What defendant had done was not only distinctly contrary to the provisions of the Metropolitan Building Acts, but a direct and positive violation of the injunction which had been granted. Notwithstanding the action brought by the plaintiff, notwithstanding the notice, and notwithstanding the order of this Court, the defendant thought he would do as he liked. The acts of defendant had been entirely wrong, and there had been no defence except that of acquiescence by plaintiff. That defence entirely failed, and therefore as regards the party wall there must be an injunction and the defendant must pay the costs of it. He must also pay the costs of the motion to commit, which now came on with the trial. The plaintiff had also shown that he was entitled to some damages, which he would assess at £50. As to the alleged interference with the plaintiff's ancient lights, the plaintiff said that there was such a material diminution of light as to render his house less fit for the use to which a house of that kind was ordinarily put. But his lordship had never heard weaker evidence on that point than had been put forward in this case; therefore that part of the action must be dismissed with costs. The costs of each party would be set off.

**ACTION FOR LIBEL AGAINST A REDRUTH ARCHITECT.**—Before the acting Under Sheriff for Devonshire (Mr. E. H. Houlditch), at Exeter on Thursday, the 23rd inst., John Short Sanders, commission agent and commercial traveller, of Newton Abbot, brought an action to recover damages for libel against the Western Manufacturing Company, of Redruth, Cornwall. The Hon. Bernard Coleridge, M.P., represented the plaintiff, and Mr. James Hicks,

V.P.S.A. (who carries on the business of the defendant company), conducted his own case. Judgment had been allowed to go by default, and it was for the jury to assess the damages. Mr. Coleridge said the action was brought by the plaintiff against the Western Manufacturing Company, of which Mr. Hicks was the sole proprietor. Mr. Sanders was a commercial traveller residing at Newton Abbot. The defendant represented the Western Manufacturing Company at Redruth, and was also an architect in a good way of business, and further acted as a commission agent. In April, 1888, Mr. Hicks, being desirous of pushing the business of the Western Manufacturing Company, a confectionery business, employed plaintiff to sell his wares throughout Devon. Up to the end of October sales amounting to £251 12s. 7d. had been effected, the commission due being £25. There was no secret about the plaintiff retaining the money, because he sent in accounts of the sums received with the names and dates. This went on to December 10, and the sales then amounted to £325 14s. 1½d., and the commission to £32 11s. 6d. On that day plaintiff went to Paignton, when a client showed him a letter, written on the company's note paper, to the following effect:—"Sir, Mr. J. S. Sanders does not now represent us, and you will please not pay him any money." The imputation was that the plaintiff could not be trusted. On the 17th December the defendant sent the following telegram to Sanders:—"If you attempt to collect another account we will have you arrested." The most serious libel was contained in a letter in December, 1888. It ran as follows:—"We hope there will be no trouble arising out of your sending money to Sanders, but on the face of it it has a serious aspect. We think you should have placed yourself in communication with us, as you must have known the goods were ours. We need scarcely say we have received no remittance from Sanders in respect of those goods. We hope you will do what you can quickly to close affairs." Defendant said he had received complaints from customers as to the mode in which the plaintiff had conducted his business, and thought himself justified in writing to his clients on the subject. The defendant disclaimed his intention of allowing judgment to go by default. This was due to an oversight arising out of his answers to interrogatories. The jury assessed damages at £50. The defendant intimated his intention of applying to a higher Court for a new trial on the ground of misdirection.

**SERIOUS CHARGES AGAINST A SURVEYOR.**—At Westminster Police-court on Saturday, John Hill, 41, a surveyor, of Broadstairs, formerly an architect and surveyor at Brighton, was brought up in custody, having absconded from his bail, to further answer charges of embezzlement and forgery. The prisoner, from March, 1888, until the beginning of last year, was associated in a business capacity with a Mr. Hans Scharien, a builder and house agent, of South Kensington. Mr. Scharien alleged that the accused received a considerable sum of money on his behalf, and that he endorsed a cheque "H. Scharien and Co." without authority and misappropriated the proceeds. Cross-examined, prosecutor admitted that accused acted as an auctioneer for him, and that he was authorised to endorse documents other than cheques, also that some remuneration was due to accused. Sergeant Church said prisoner was taken in custody last February, and while under remand from this court absconded. Two persons, who each bailed him in the sum of £30—one being a small tradesman, who accepted the responsibility for a small consideration, and had never seen the prisoner—had to go to prison for 14 days in default of paying the amount of their forfeited recognisances. When originally charged, prisoner said part of the money belonged to him, but he knew he had no business to receive it. On Friday witness re-arrested him at Ramsgate. The prisoner was remanded in custody.

A number of residences are about being commenced at Smethwick, Bloxwich, near Walsall, and near Solihull, Birmingham. These houses will be of a size and character adapted to the requirements of clerks, &c., and of the higher class of skilled artisans. The front elevation of these buildings is intended to be of a Gothic character, and ornamental stone, woodwork, brickwork, and metal work; Minton's tiles, buff and red terracotta, and other decorative accessories will be introduced. The total cost of erection is estimated at about £26,000. The architect is Mr. John Statham Davis, of 53, Newhall-street, Birmingham.

William Chatterton Milton, aged 34, of Park-street, Stoke Newington, manager to the Hitchings Patent Plaster Company, pleaded guilty on Saturday, at the Dalton Police-court, to forging an endorsement on a cheque for £28 14s., with intent to defraud his employers. The prosecutors, through their solicitor, asked that the case might be dealt with as one of embezzlement, and they strongly recommended the prisoner to mercy. Mr. Haden Corser assented, and ordered him to be imprisoned with hard labour for three months.

### WATER SUPPLY AND SANITARY MATTERS.

WORSLEY, NEAR MANCHESTER.—An inquiry was opened on Wednesday, 22nd inst., at the Court-house, Worsley, before Col. W. M. Ducat, R.E., with reference to an application of the Barton Rural Sanitary Authority to borrow the sum of £4,000 for private street improvements at Boothstown and Walkden. There were present many property owners who objected to some of the works as unnecessary. The inspector said the authority was compelled as a public body to carry out the law. The authority was represented by Mr. J. W. Whitworth (deputy clerk), Mr. C. C. Hooley, C.E. (surveyor), Mr. Geo. Burgess (chairman), and Mr. Jas. Evans (member). Mr. Thomas Berry, C.E., represented the Trustees of the late Duke of Bridgewater (ground landlord), and Mr. F. Booth, secretary to the Ratepayers' Association. The clerk stated that the money was to be repaid in ten years. The surveyor explained the works proposed by the authority. After hearing the evidence the inspector visited the streets in question. He will report to the Local Government Board.

### CHIPS.

The Aberdeen town council received a report on Monday from Dr. Matthew Hay, the medical officer of health, condemning, as an "unhealthy area" under the Artisans' and Labourers' Dwellings Acts, a district lying between the Ship-row, Chapel-lane, Virginia-street, Marischal-street, and Castle-street.

Professor Baldwin Brown, of Edinburgh, inaugurated a course of lectures on art in the Terrace Good Templar Hall, Paisley, last week. The lectures are in connection with the University Extension Scheme.

The strike of brickmakers in the East Worcestershire and Staffordshire Districts, which commenced on Monday week, terminated on Friday, all the employers having conceded an advance of wages of 15 per cent.

New buildings, erected by the Luton Board in extension of Old Bedford-road School, were recently opened by the Right Hon. A. J. Mundella, M.P. The school originally consisted of three rooms, and was for girls and infants only. The main room has now been enlarged, and several new rooms have now been added. The school which previously provided for 218 children, now accommodates 250 boys, 250 girls, and 279 infants. The school furniture was supplied by Messrs. Hammer and Co., of London.

The Bishop of Colchester on Saturday consecrated the new church of St. Clement's, Ilford, built to meet the needs of the increasing population on the north side of the town. The first part of the design only has been carried out at present, owing to want of funds.

The Directors of the Cowbridge and Aberthaw Railway met at Cardiff on Thursday, when the contract for the construction of the line was given to Mr. W. H. Mathias. The first sod will be cut at Cowbridge on Friday in next week, the 7th prox.

The annual dinner of the Cardiff Master Builders' Association was held at the Angel Hotel, Cardiff, on Friday evening, when Alderman D. Jones presided. About 90 members sat down. Mr. Edwin Seward, R.C.A., proposed "The Cardiff Builders' Association," to which the chairman and Mr. Shepton responded, and the health of "The Architects of Cardiff" was acknowledged by Mr. J. P. Jones.

At a meeting held at the rooms of the Society of Antiquaries, Mr. John Evans, D.C.L., P.S.A., in the chair, it was resolved that subscriptions be invited for the purpose of striking a medal in honour of Mr. Charles Roach Smith, and that the balance of the fund be handed to him, in recognition of his life-long and valuable services in the cause of archaeology. Subscriptions should be forwarded to Mr. George Payne, F.S.A., hon. secretary and treasurer, The Precinct, Rochester.

New married quarters for the Royal Marines are to be erected at once at Chatham. Messrs. Naylar and Son, of Rochester, have secured the contract. About £6,000 will be spent.

Messrs. Archibald Smith and Stevens have been intrusted with an order for two of their "Reliance" hydraulic lifts for the extension of Brown's and St. George's Hotel, Albermarle-street. The same firm have in hand similar lifts for the Norfolk Hotel, South Kensington; Queen's-gate Mansions, Kensington; Montague Mansions, Bloomsbury; Avenue Mansions, Shaftesbury-avenue; and the French Hospital, Charing Cross-road. During the past month they have completed "Reliance" lifts for the Camberwell Infirmary, the Middlesex Hospital, Baron D'Erlanger, and Mr. R. Benyon, the two latter for their town houses.

Mr. F. W. Maxwell, of 29, Princess-street, Manchester, having successfully passed the requisite examination, has been admitted as a Fellow of the Surveyors' Institute, London.

### Our Office Table.

The architects of Cardiff and district and their assistants met at a dinner at the Park Hotel, Cardiff, on Wednesday evening, the chair being occupied by Mr. J. P. Seddon, F.R.I.B.A. This gathering, which is intended to become an annual event, was the outcome of the visit of the Society of Architects to South Wales in the autumn, and the Society was upon this occasion represented by its secretary, Mr. G. A. T. Middleton.

In celebration of the extension of the electric lighting at the British Museum from the reading-room and courtyard to the various galleries, a private view of the museum was given on Tuesday evening by Mr. E. Maunde Thompson, the chief librarian, and was attended by over 1,000 visitors. Both arc and glow lamps are employed, the sculpture galleries on the ground floor, and the Egyptian, Archaic, Etruscan, and White Memorial galleries above being lighted by the former system, 126 arc lamps in all being used; while rows of incandescent lamps—127 altogether—are introduced into the Greek, Pan-Athenæan and Ethnological galleries. The installation is a success, the objects being fully illuminated, with an absence of glare. The western gallery was, however, closed, the explanation given being that the current was not sufficiently powerful to supply all the lights required. It was noteworthy that the colours of exhibits were apparently unchanged by the arc lights, whereas the incandescent lamps gave a distinctly warm glow. All the lamps on both systems are supplied from dynamos charged by engines of 200H.P., the machinery being in duplicate and placed in the basement, the main lines being laid outside the building. Messrs. Siemens Brothers, who effected the original installation five years since, have carried out the present work, under the direction of Mr. W. H. Preece, F.R.S., of the Post Office, and Mr. John Taylor, architect to H.M. Office of Works. Mr. Pullman has been the clerk of works. The engines were supplied by Messrs. Marshall, Sons, and Co., of Gainsborough.

The committee deputed by the Staffordshire County Council to elect a chief surveyor of main roads met on Tuesday week, and had before them the seven candidates who had been selected from the 123 applications originally received. The selected candidates were—R. E. W. Berrington, borough surveyor, Wolverhampton; J. T. Eayrs, borough surveyor, West Bromwich; G. A. Hutchins, Cardiganshire; Joseph Lobley, Hanley; James Moncur, Kirriemuir, N.B.; F. H. Phillips, Cardiff; and S. S. Platt, Rochdale. The committee reduced the number further to three—viz., Messrs. Berrington, Hutchins, and Moncur, and in the result Mr. Moncur received the appointment. The salary is £800, to include travelling expenses, the rent of an office at Stafford, and the wages of a clerk. The chief surveyor will have the charge of nearly 700 miles of main roads, and it is intended to divide this length of road into six or seven districts, to each of which an assistant surveyor will be appointed, at salaries to be fixed by the Council. The chief surveyor will have the power of appointment and dismissal of these subordinates. Mr. Moncur was trained as a road surveyor, first in the office of Mr. Blackadder, C.E., Dundee, and afterwards with Mr. Grant, C.E. and road surveyor, Kirriemuir, whom he succeeded in 1880. Since that date he has had full charge of the roads in the Forfar district of Forfarshire, extending to 312 miles, and has gained experience in maintaining roads, forming new roads, erecting bridges, drainage works, and all the other operations connected with roads. Mr. Moncur will enter upon his new duties on the 10th of February, and proceed to the arrangement of districts and the organisation of his staff, in order that all the machinery may be ready for the taking over of the roads by the Council on the 1st of April.

The late Mr. John McArthur, jun., architect, of Philadelphia, the architect of the new City Hall at Philadelphia, which is probably the second building in importance in the United States, died at his residence, 4,203, Walnut-street, Philadelphia, on the morning of the 8th Jan., of heart disease, accelerated by influenza. His death was not altogether unexpected, for his health has been failing for several years, and during the last six months he has frequently been compelled

to remain at home for days together. He was at the new City Hall for the last time on New Year's Day, and then caught a cold that aggravated his delicate state, and, to the great grief of all who knew him, proved ultimately fatal. He was about 63 years of age.

MESSRS. HUDSON AND KEARNS send us specimens of their coloured office calendars gorgeous with peacocks, and suggestive of Time's rapid flight with its light-winged dove. The views of Streatley Bridge and Bisham Abbey are very nice, and altogether the calendar is one of the nicest and most artistic we have seen. The little ivory pocket calendar and memoranda tablet is also neat and tasteful.

### MEETINGS FOR THE ENSUING WEEK.

- MONDAY.—Royal Academy. "Roman Architecture," No. 3, by Prof. Geo. Aitchison, A.R.A. 8 p.m.  
Royal Institute of British Architects. "The Renaissance in Northamptonshire," by J. A. Gatch. 8 p.m.  
Society of Arts. "The Electro-Magnet," Cantor Lecture No. 3, by Prof. Silvanus P. Thompson. 8 p.m.  
Liverpool Architectural Society. "Mouldings," by T. W. Haigh.  
Leeds and Yorkshire Architectural Society. "Mural Painting," by F. Suddards.
- TUESDAY.—Institution of Civil Engineers. "Bars at the Mouths of Tidal Estuaries," by W. H. Wheeler, M.Inst.C.E. 8 p.m.  
Manchester Architectural Association. "The Houses of Queen Elizabeth's Courtiers," by J. A. Gatch, of Kettering.  
Glasgow Architectural Association. "Influence of French Renaissance on Modern Architecture," by H. D. Walton.
- WEDNESDAY.—Civil and Mechanical Engineer's Society. "Recent Progress in Sewage Treatment," by C. H. Cooper. 7 p.m.  
Carpenters' Hall Free Lectures. No. 1. "Architecture in All Ages," by Banister Fletcher, J.P., D.L. 8 p.m.  
Society of Arts. "High-Speed Weaving and Knitting without Weft," by Arthur Paget. 8 p.m.
- THURSDAY.—Royal Academy. "Roman Architecture," No. 4, by Prof. Geo. Aitchison, A.R.A. 8 p.m.  
Edinburgh Architectural Association. Paper by John Kinross. 8 p.m.
- FRIDAY.—Institution of Civil Engineers. "Reclamation of Land from the River Tees," by Colin P. Fowler. 7.30 p.m.  
Royal Institution. "The London Stage in Elizabeth's Reign," by H. B. Wheatley. 9 p.m.  
Society of Arts. "The Utility of Forests and the Study of Forestry," by Dr. Schlich. 5 p.m.

### Trade News.

#### WAGES MOVEMENTS.

SMETHWICK.—A well-attended meeting of carpenters and joiners of Smethwick was held on Friday night, in connection with the local branch of the Amalgamated Society of Carpenters and Joiners, for the purpose of considering their present position in the trade. Mr. W. Roe presided, and remarked that he hoped all the non-association men would join the society at once and make their organisation a strong one. In Smethwick they were being paid a rate of wages 1d. per hour lower than the Birmingham men received. Mr. McNeil submitted a code of rules relating to the number of working hours (the total hours for work being fifty-four), the rate of wages to be paid for ordinary and overtime, &c., which were unanimously adopted. Addresses were delivered by Mr. Langford (secretary) and others.

DUNDEE.—At a largely-attended meeting of the Dundee and District Master Builders' Association, held in Mathers' Hotel, Whitehall-street, the schedules issued by the School Board architect for tenders for the Leff-road school, Loches, were under consideration, and it was unanimously resolved to decline to tender except according to the general condition of contracts as agreed to between the Dundee Institute of Architecture, Science, and Art and the builders of Dundee. The meeting expressed regret that an attempt should be made to break through this arrangement, and hoped that the Association would not again have to complain on this head, and instructed the secretary to send a copy of the resolution to the School Board architect, and to the secretary of the Dundee Institute.

The Derbyshire County Council have resolved to take under their own control from April 1st the whole of the main roads in the county, 900 miles in length. Six district surveyors will be appointed to act under the direction of the present county surveyor. Heretofore the main roads have been managed by 173 local authorities.

## COMPETITION DESIGNS.

WHETHER better results attend the giving of a commission to one architect, or a competition in which a large number of the profession are invited to send in designs, is a question that cannot possibly be answered under the present conditions. Are architects who compete more or less able than those who are content to depend on their private practice? Do the chances of competition make it probable that a more thoughtful or skilful design can be acquired than by instructing a professional architect of known ability and experience to prepare one? The chances in favour of obtaining a better design by competition are increased by the number of those responding and the competency of the competitors; but these two elements are uncertain unless the inducements to enter the lists are great. For important public buildings, the chances are decidedly in favour of competition when properly conducted, even if some of the *élite* of the profession remain out of it, for the simple reason that a certain number of able architects, unknown to fame, are inclined to try their luck. So very much, however, depends on the terms of invitation and the discretion of the committee of selection or their assessor, that it may be safely asserted that the contributions of unknown talent and the chances of securing the best designs may be practically thrown away or lost. For example, if out of one hundred designs sent in there are a dozen sets which show skilful planning or artistic ability, and those dozen are overlooked in favour of a showy or popular set, all the advantages of competing are flagrantly thrown aside, and it would have been much better if the committee had taken their requirements to a competent architect and have instructed him to prepare a design for their approval. They would, at any rate, be able to give him their instructions without fear or favour, and he, on his part, would be able to avail himself of the advice of the individual members, instead of a formal set of printed instructions that may be, and often is, silent on points of the greatest moment to an architect; he would at least not be debarred from asking questions, and be able to adopt or suggest views of the utmost value to him in preparing a well-thought-out design. A strange perverseness seems to control the destiny of our competitions for public works. A public invitation is decided upon, an assessor is appointed to aid the committee, but after the expense and labour incurred, the safeguards and conditions necessary to secure the best selection are one by one set aside or ignored, perhaps the assessor's recommendations unheeded, the choice made being a hundred times worse than if a single architect had been commissioned to make a design. The advantages of competition are thus completely lost sight of.

Compared with the procedure adopted by an architect acting under specific instructions from a client, the mode of a competing architect is adverse to a thoughtful consideration of the problem. He has certain instructions more or less arbitrary and ambiguous set before him, which he cannot alter or modify without running the risk of being disqualified; the accommodation is given in a schedule form of areas, and he has sometimes a rough plan furnished as a guide as to the arrangement suggested. In many designs submitted under these conditions we see a tendency to follow them implicitly, competitors adopt the plan with-

out further consideration, and also the superficial feet scheduled. Little original inquiry or thought is bestowed to modify and improve, in short, there appears to be a presumption that the nearer the instructions are followed the better. Mr. Waterhouse, R.A., in his judicious remarks to students at the Institute, spoke of the desirability of hampering competitors as little as possible with vexatious restrictions, leaving them free to solve in their own way the problem before them. It will be well if this advice is acted upon by those who draw up instructions. As they are generally worded, they not only restrict invention, but leave on the minds of many competitors a strong impression that they must not be deviated from, that the rooms must be of a certain scheduled size, and located as shown on the plan. The result can be apprehended. Having drawn the plan to scale according to the dimensions given, nothing more is needed than to fill in the details, and furnish as attractive-looking an elevation as possible. We have had the opportunity of examining numerous competition designs, and can speak from personal experience of the timid manner in which many competitors set to work on their plans, and how closely they follow any suggested scheme. Only a few of the bolder geniuses venture to show modified arrangements, which they do so as often to their advantage as they risk the innovation. Mr. Waterhouse rightly said: "I would have every competitor put as nearly as may be in the position of an architect acting for a private client who, though he may have suggested his requirements, would probably listen to his professional adviser if he gave good reasons for not literally adhering to them in all cases." The remark clearly bears out the suggestion previously made that if competition-designing is to be successful, it must be free and spontaneous, and that the procedure followed by a privately-instructed architect should be kept in view. Schedules of sizes for rooms should be only suggested, so that each competitor would be free to vary the dimensions to make his rooms agreeable in proportion. Mr. Waterhouse, in speaking of the Sheffield Municipal Buildings' designs, referred to the anxiety of many competitors to adhere to the suggested dimensions, by which compliance they often gave rooms of intolerable proportions, such as 50ft. by 30ft. by 12ft. 6in. high. We have seen many worse proportions than 50ft. by 30ft. The other day we saw an assembly-hall 80ft. by 30ft.; often a disagreeable nearness to a square, which has neither the oblong nor the exactly equilateral to recommend it—in fact, the result of dividing the space at disposal in the easiest manner to comply with the instructions. Now, we venture to say that a plan of this description, though common enough in competitions, would not be prepared by an architect whose reputation was worth anything, and who was instructed by a private client. The want of study of plan is seen in a great many other things—such as halls and staircases. These are often painfully neglected; at other times we see them swallowing up an immense area, completely sacrificing the rooms or offices of important departments, which ought to be got on the ground floor, but which are thereby placed a floor or two higher up, much to the detriment of the design. To think of double flights or twin stairs when the space is too cramped for an easy ascent to one staircase is, as Mr. Waterhouse pointed out, inexcusable folly.

A suggested sketch plan, by excluding the architect's own attempt to solve the problem, is, to a large extent, answerable for these faults. We often see that the competitor has simply followed the plan, actually adopting the same spacing for rooms, halls, and entrances. An architect instructed by a client would certainly resent a plan thrust upon him to follow. He would use his own

discretion, discuss the defects of such a plan, show how it could be improved, or a better arrangement made; but the competitor has no appeal—he has to simply follow his instructions. There is no opportunity afforded him to discuss the merits of a scheme; he must act in accordance with the terms or retire. It is almost impossible to obtain thoughtful designs under such a system. The assessor is tied to the terms, and cannot justly depart from them without apparent injustice to others. For these obvious reasons architects should, by combining together, endeavour to alter this arbitrary dictation of plan and requirements, as quite prejudicial to the end in view of competition—that of obtaining the most skilful design at a given cost. If promoters saw that professional men of competence would not respond unless they were wholly free to act upon their own knowledge, and would not be tied by vexatious restrictions, a healthier and more beneficial régime would be soon established. As we have said before, the conduct of competitions is what those who enter into them are content to make them or allow them to be—indeed, it is absurd to indulge in rhapsodical outbursts of indignant remonstrance against committees and boards for unfair decisions and dealings as disappointed competitors are wont to do.

Were we to sum up the errors and weaknesses of competition design, we should discover that they were mainly the results of rapidity of execution and of the want of personal attention and thought. They are such faults as we do not find in designs prepared in the ordinary manner. The plan roughly sketched is given to a lot of clerks to work out, the elevations and perspective sketches are handed over to draughtsmen to make the best they can of them. Between them a set of drawings are prepared that bear evidences of disagreement in several particulars—elevations that do not agree with the plans, plans that show no careful revision, that are full of errors and crudities, while the general absence of detail and finish show the work has been done piecemeal by different hands not under the immediate control of one mind. One great merit of dividing a competition into two parts—a "sketch" and "final stage"—is that there is much less of this crudeness and imperfection of design possible. The "preliminary or sketch" designs are the work of one hand—the architect himself—who has time to think over and revise his arrangements between the first and final competition. There is evidently more likelihood of obtaining studied designs by this mode than when only one set of finished drawings are to be sent in on a short notice.

Let us look to some common faults of design. Of those noticed in designs for public buildings, one of the most prevalent is in not selecting a prominent or desirable position for the chief apartments. Instead of making the large hall, council-chamber, or court a key to the whole, it is placed on one side or allowed to take a chance position on the plan, often unemphasised in the elevation. In municipal buildings one or other of these ought to constitute the nucleus of the whole, and be assigned a position that will give the building a distinctive character. Generally this is to be found on one of the main axes, either in a line with the principal entrance, or in the centre of one of the chief fronts. The Manchester Town Hall is an example of an open triangular block with the public hall in the centre—undoubtedly the best position that could be given to it. The Dewsbury Public Hall Buildings, which occupy three sides of an irregular site of wedge-shape, has the hall placed on a central axis opposite the entrance.

The Fulham Vestry Hall Competition showed great indecision. Some of the competitors put the public hall in front, others in the rear parallel to one side of the site, while a large number placed the axis of hall obliquely to the front block. The site being

of irregular form—tapering behind—there was not much choice between these alternatives; but for regular-shaped sites one or other of the main axes can be chosen, and if the end or flank can be expressed externally, a good central feature may be made of it, to which the other buildings or offices can be attached. The Sheffield Municipal Buildings site, which is of a triangular shape, offered one or two good positions for the council-chamber; but few seem to have availed themselves of the one which a council-chamber ought to have—retired from traffic and noise. No less common is it to find the rooms and offices badly lighted, either from small areas or through windows badly placed, often too low to allow the light to enter with the best advantage. What can be expected from windows several feet below the ceiling, opening into an area or court surrounded by lofty buildings. In the hurry of plan preparation, a small court is expected to do wonders to give light to large offices. Failing a window in a front, a small area is contrived, and windows introduced opening into it, and the difficulty is supposed to be met. The inefficient lighting of corridors is a fault only too common. If a side light or two can be eked out, or a borrowed light through some room obtained, no more trouble is taken—the ends of the corridor may be perfectly dark just where the light is wanted. Borrowed lights through rooms are one of the weak points of designs prepared by novices. In several recent municipal offices competitions we have found corridors entirely lighted through the offices in front. If space allowed us, we could name many other of the weaknesses of designs submitted in competition. We are satisfied to dwell on a few of the more prevalent. We might have said a great deal on the subject of adapting buildings to their surroundings, or the want of more care in designing elevations and roofs to principal thoroughfares, or towards boundaries that one day are likely to be exposed to view by the removal of adjoining premises, and on the absolute necessity of making perspectives from a point of view from which the group of buildings or design can be seen, instead of from imaginary positions which never can be utilised. On the latter subject certain restrictions as to the height of eye, distance from picture plane, and angle of line of sight, ought to be laid down by promoters.

#### HOUSE-LIGHTING.

ALTHOUGH architecture does not deal directly with such services as those of water, gas, and electricity, the professional adviser is often required to prepare specifications and obtain estimates for these requirements. It may be true that the callings of gas-engineer and electric-light contractors leave the architect nothing to do except to select the positions for lamps and the ornamental fittings, pendants, and electroliers; that the electric light engineer undertakes the inside "wiring" of the house, contracts for the putting up of the fittings, and connects the wires to the mains of the supply company; but those duties have to be performed with some care and attention, and as the engineer and contractor are often one and the same person, it is reasonable that the architect should be able to exercise some control, and, for this purpose, that he should at least know the proper manner of carrying out the work. He specifies the trades of the bellhanger, the smith, and ventilating engineer—why should he not also specify the work of the electric-light engineer? There can be no reason whatever, except that the new profession of electric-light engineer is one that entitles its followers to the respect due to specialists. The subject is, at any rate, one that the architect will have to master, and as far as it goes, there is not

much to learn to make oneself tolerably proficient in the application of electricity to lighting purposes; therefore it was opportune that the Society of Architects devoted one evening last week to hear a paper read on the subject of "Electricity in the Dwelling," by Mr. E. Percival Allam. As the subject is not a very familiar one to many architects, it was excusable that the author of the paper should speak on a few of the elementary facts of electrical science, such as the chemical battery, the theory of electro-magnetism, electrical induction, Faraday's experiments with magnets and coils, and so on.

As a clear introductory statement of the principles of electro-magnetism and the production of a current, Mr. Allam's paper, reported in our last issue, will be read with interest by all; but it may be regretted that so little time was left for the discussion of details of a practical kind. What the architect naturally desires to know is how the internal mechanism of an installation should be arranged; he wants information of a practical kind as to the proper "wiring" of a building, the number of lamps necessary in certain rooms, their distribution and fittings. These are just those items which an elementary paper does not supply. Speaking of the number of lamps required to light a given area, Mr. Allam was justified in remarking that the only method is to take good oil lamps and place them round the room until the desired effect is obtained. We know of an instance where a certain number of incandescent or glow lamps were ordered to light a large room, but after they had been fitted it was found they were unequal to the task, and gas lamps were called into requisition to supply the deficiency. The walls had been painted rather too dark, and absorbed the light. The first thing the architect who is consulted in the matter should do is to decide on the positions of the lamps in the room. For effective and uniform lighting, no doubt it is desirable, as pointed out by Mr. Allam, to distribute the light round the walls at certain intervals, "about 3ft. from the walls and from 7 to 10ft. from the floor," but for artistic effects, and even for architectural reasons, we think grouping the lights is an advantage. Following Nature in the distribution of sunlight, we think uniformity of illumination is undesirable, except in offices and workrooms, where the light ought to be evenly distributed amongst the employés or clerks. In those galleries at the British Museum just lighted by incandescent lamps, we noticed, at the inauguration the other evening, that the regularity and closeness of the lines of lights produced a painful and glaring effect; but in these rooms, where exhibits of works by uncivilised races are displayed, an excessive and otherwise too uniform lighting scheme is, perhaps, permissible. As Nature gives us light and shade and various gradations, so we think there is a variety and charm to be obtained in lighting a room, say a drawing-room or a large hall, by groups of lamps either in the form of electroliers or brackets from the walls. For decorative effects the grouped plan is the best, as we then obtain a gradation of shade on the walls. The architect is the right person to select those points of an interior, particularly if it is irregular in plan, which he thinks should be shown up or illuminated—as, for example, in throwing into strong light and shadow any sculpture, or columns and capitals; and he may have like reasons for burying in gloom or shadow some other feature that he wishes to conceal. It appears to us that many of our modern hotel and restaurant interiors are illuminated on the principle of supplying as many pendants and electroliers as possible. The light may be well distributed, but the architectural effects have not been consulted. Strong shadows, of course, are to be avoided, especially those which are

cast on the lower parts of the walls and floor, and the pendant system of lighting minimises these objections to a large extent.

Speaking of hanging lamps, Mr. Allam referred to the insulated twin wires which are twisted and brought down to the lamp, and all covered with silk to any suitable pattern; he also spoke of this "line of straight wire being relieved in the middle by glass beads and ornamental metal sprays, &c." Pretty as some of these sprays and leaf entwines are, they are certainly not artistically appropriate, and some of the ornamental metal leafage with tendrils imitating natural ivy and other climbing plants we have seen are to be avoided. Many artistic forms of wrought iron and hammered brass and copper are, as Mr. Allam says, available without recourse to naturalistic imitations. Several useful suggestions were given. The use and value of accumulators or secondary batteries for storing current from which to run the lamps when the dynamo is not at work or charging are undoubted. The proper mode of wiring a house, the undesirability to leave the work till after the house is finished and decorated, causing the rooms to be knocked about, the unsightliness of casings being fixed to the wall instead of being buried in casings behind the plaster are matters of moment to the architect. The employment of a casing that can be fixed to the wall and made to harmonise with the decorations is one of the points to be attended to, and we agree with Mr. Allam when he said a better plan than running the casing on a ceiling is to lay it across the joists under the floor above, and to bring the wires through the ceiling. Due insulation of the wires, their distance apart, and the insertion of fuses are precautions that cannot be too strongly enforced in large establishments. On the whole, electric lighting, free from the many disadvantages and dangers of gas, especially the over-heating of rooms, and the noxious gases which are given off so destructive to all kinds of decoration, pictures, and books, lends itself with facility to the architect's purposes, especially by the ease with which the fittings can be applied to ornamental features, such as capitals, as the wires can be bent and twisted in any manner, which is quite incompatible with gas tubing and the rigid and stiff forms of the fittings used. The subject is one that is forcing its way into general recognition, and the profession will be acting wisely in making themselves familiar with the arrangements and details of electric lighting installations.

#### ARCHITECTURAL BRICKWORK.—XXVIII.

##### ARCHES.—DOOR OPENINGS.

FEW situations are more favourable to architectural brick effect than that of the doorway. In a thick wall by simply forming two or three recesses in the jambs, and building them with well-selected bricks, either plain or moulded, an ornamental and imposing opening can be obtained. Take, for example, the plain brick semicircular arched doorways found in old buildings of the Georgian period, where we see the doorway recessed a brick or half a brick from the outer wall face. The recess itself is composed of jambs, usually one brick wide, having an arch over it of the same depth. The outer, or face arch, or upper arch above the recess, is generally a brick and a half in thickness. A third recess or face imparts a still more solid effect to the work capable of architectural ornamentation. Very rich effects are obtainable by this mode of recessing the arches and jambs. We have a notable and effective archway of several recesses or members in the great arched entrance to the Natural History Museum at South Kensington, in which

terracotta shafts are introduced. Many of the Romanesque brick churches, and the deeply-recessed portals of some of the French cathedrals, show the beauty and effectiveness of this treatment, though in other materials. The membered brick jamb has a beauty of its own, for the ever-varying lines and curves of its horizontal joints and radiating arch joints add much to the appearance of a recessed doorway as seen in perspective. Take, for example, the brick contoured jambs of many Verona buildings, like those we represent in sketches 4 and 5, and notice the play of these jamb and arch lines, and the varying effect of shadow and reflected light in them. We hope to give a few other sketches of jambs and arches of this character.

#### CUTTING ARCH BRICKS.

Particular care is necessary in constructing these arches over and within recesses, as they are unconnected by any tie; there is no bond between the upper and outer face arch and that over the inner doorway, as each arch carries its own thickness of wall over. Bricklayers pay particular attention to the outer faces, to rub them smoothly, and make the joints neat; but inside, the bricks are often hollowed or cut away, so that the pressure is brought to bear on the fine joints just at the outer edges, which are sure to fracture or crumble. The arch often bulges out in front from the lack of resistance in the inside joints; in other cases we see gauged bricks drop down below the intrados line, destroying the appearance of the arch. For brick arches which are only half a brick in length, whole bricks make stronger work than when every alternate brick is made up of two bats. We shall show other instances of cut and moulded arches.

#### FLAT ARCH SKEW-BACKS.

In Fig. 1 we show how skew-backs are formed for straight arches abutting against

each other on a mullion. The skew-backs are cut to an angle of 60°, and the mullion is one and a half brick, or 14in. wide. The voussoir bricks are cut and rubbed to the proper shape, the joints converging to the apex of an equilateral triangle, the base of which is the soffit of the arch. These flat-gauged arches are generally cambered to allow for any settlement, the soffit having

a rise of  $\frac{1}{4}$  in. to the foot. In setting out and cutting of this arch the skew-back is first given, and the lines of extrados and springing are drawn. Then from the centre line of arch the half-width of the centre brick is set off, and from these points of width lines are drawn to the centre of arch, and the face mould of key is the result. Moulds are made longer than the key, and marked at the soffit line. Then the moulds are traversed along to the skew-back, the marked line being always kept to the soffit or springing line. The bevels are pencilled on the mould, and the length of bevel of each course being thus obtained, the bricks can be cut to the desired length and bevel.

Below Fig. 1 we show plans of successive courses of the mullion, which is a brick and a half wide.

#### ANGLE MULLIONS.

For bay windows the mullions at the angles are generally of cut brick. In sketch 2 we show the sides making an angle of 45°. By reference to the diagram it will be seen that on one course the bricks meeting at the angle

*a* and *b* are cut to a bevel at the end, and another diamond-shaped brick, *c*, is introduced between them to form a bond. In the next course the bricks are reversed, the closer, *d*, being on the other side. Unless the bricks were cut there would be no tie. Sometimes, however, pieces of hoop iron are used to tie the front and back bricks together. At the junction of side of bay with main wall an arrangement is shown for the same purpose, the dotted lines indicating the following course and showing how the straight joint at the junction of the two walls is broken in the successive course. Bricklayers vary these methods. In 3 we show the elevation of the angle mullion.

#### EXAMPLES.

In sketches 4 and 5 we illustrate two windows, one from the Cathedral of Monza, given by Mr. Street, and the other from Verona. The Italians in their treatment of brickwork have shown themselves masters of

effective arch moulds and jambs; their bright, sunny climate is favourable to the deeply recessed arch with its receding members throwing one portion, as the soffits of arches, into deep shadow and lighting up another portion by gleaming lines of sunlight on shaft and mouldings. Hence the beauty and gradation of the deeply set windows with these groups of moulded brick members. The alternate use of brick and marble in the outer arch is a common feature in Italian Gothic architecture; also the filling up of the tympanum above the small arched lights.

#### ARCHITECTURAL ASSOCIATION.

THE eighth ordinary meeting of the Association was held on Friday evening, the President, Mr. Leonard Stokes, in the chair. It was announced that the Common Room discussion, postponed from Jan. 28th, would be held on Tuesday (next), Feb. 10, at 7 p.m., when the subject for consideration would be "A Revised Scheme for Architectural Training," to be opened by Mr. Arthur W. Earle. Mr. F. R. Farrow read an appeal from the Rev. T. H. le Boeuf, rector of Croyland, asking help for raising £3,000 for the completion of the works for preserving that fragment of a Benedictine Abbey Church. He also announced that visits would be paid on Saturday (to-morrow) afternoon, the 8th inst., to D'Oyly Carte's new Theatre, Cambridge-circus, and on the 22nd inst. to the Imperial Institute, now in course of erection from Mr. T. E. Collcutt's designs.

#### FREE PUBLIC LIBRARIES.

A paper on this subject, illustrated by diagrams and plans, some of which we reproduce herewith, was read for the author, Mr. E. W. MOUNTFORD, who was laid up by the prevailing epidemic, by Mr. H. D. Appleton. In the course of his introductory remarks, Mr. Mountford said that free libraries appear to have existed in England from the 14th century, and certainly others were established during the Protectorate of Oliver Cromwell. The honour of having possessed the earliest is claimed by more than one town, but Bristol would appear to have the best case. Mr. John Taylor, of that city, has shown that a library was formed there in a church before 1464, in which year it was ordained that on every festal day free access was to be given to all willing to enter for the sake of instruction, provision being made that the Prior should explain all difficult passages, and give lectures once a week, that three catalogues of the books should be provided, the Prior to pay a penalty for all books missing at the time of the annual collation of the works. A second public library was established in Bristol in 1613. The present movement in favour of free libraries originated in 1849, when a Bill empowering municipalities to erect buildings and to levy rates for the purpose was introduced by the late William Ewart, and was passed in April, 1850. Other Acts followed in 1855, 1866, and 1877, the most interesting feature of these measures to architects being that the total sum available for the erection of buildings, stocking with books, and maintenance was limited to a rate of one penny in the pound. Nothing could be more objectionable than the practice of altering existing buildings to serve as libraries. Not only was the result invariably unsatisfactory in respect of the inferior nature of the accommodation provided, but the plan had not even the merit of being economical. As a rule the first cost of such a building, plus the outlay necessary for alterations and additions, would suffice to erect a properly-arranged and well-appointed building, more convenient to the librarian, and more comfortable and attractive to the public. At Wandsworth was an example of an adapted building, and, apart from the new reading-room, it would be difficult to imagine a place more unsuited to its purpose. The author continued: In designing a new building for a public library, the chief points to be aimed at are plenty of storage room for books, sufficient light, room, and comfort for the readers, and facility of superintendence and management. A badly arranged plan will not only increase the anxiety and labour of the librarian, who is responsible for keeping order in the building, but may necessitate the employment of one or more

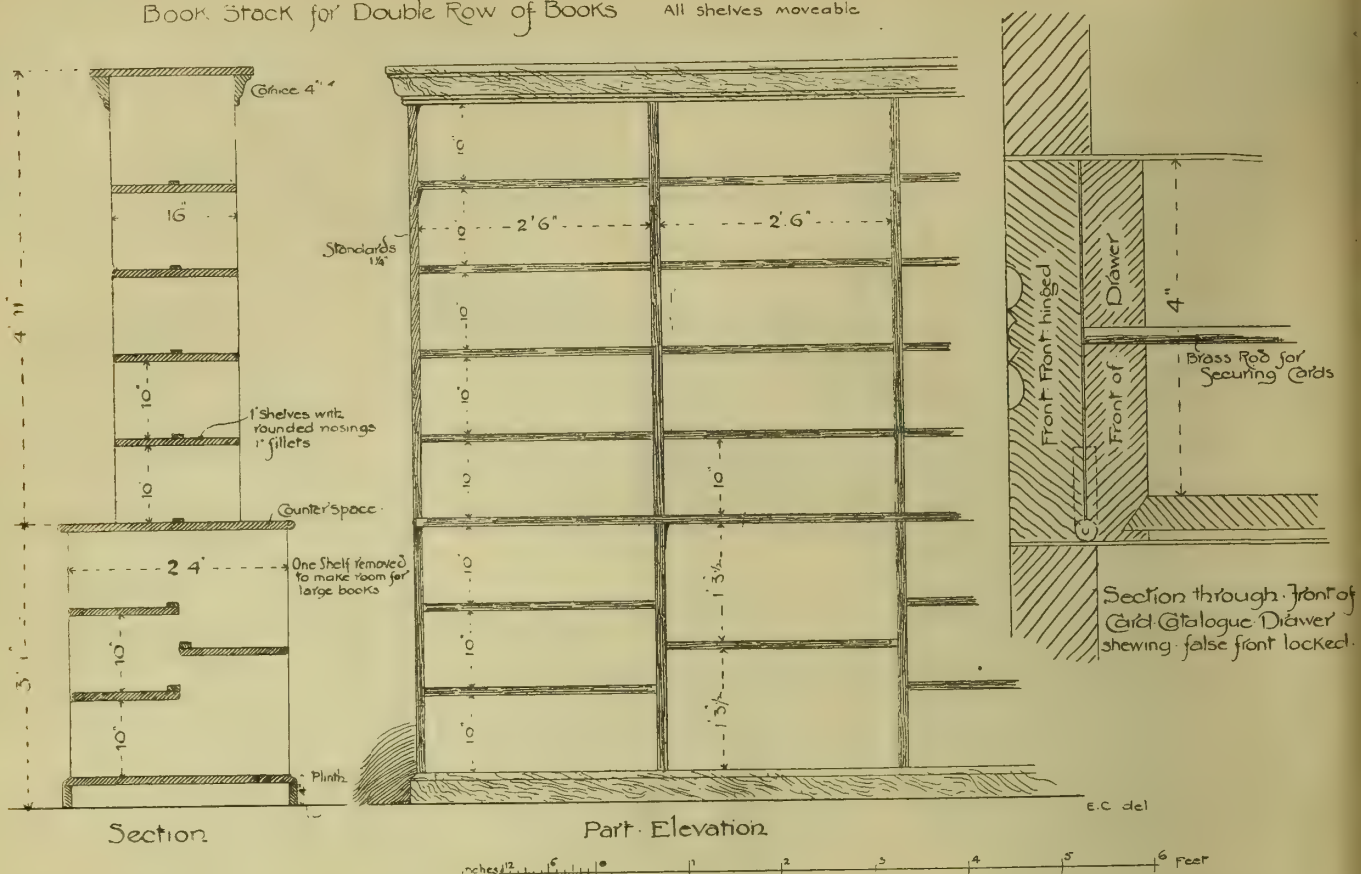

## LIBRARY FITTINGS

### Book Stack for Double Row of Books

All shelves moveable

assistants, thus adding to the cost of maintenance. In the smallest library three distinct departments are essential, a lending library, a reference library, and a reading-room. Furthermore, there should be a fair-sized entrance hall, a private room for the librarian, and, where possible, separate reading-rooms for ladies and boys respectively, all rooms being in direct communication with the hall, so that no one of them need be used as a passage to another. The reading-room should be in two parts, divided by a screen, one for newspapers, the other for magazines, reviews, and such like works, or, better still, there may be two distinct rooms. Store-rooms for books, in connection with both reference and lending libraries, will probably be required, a work-room for bookbinding and repairing, and a receiving and unpacking room. Generally a dwelling for caretaker, consisting of sitting-room, two bedrooms, and a kitchen, will be asked for, and it is an advantage to provide a room for assistant librarians. If a librarian's residence be required it should contain two reception-rooms, kitchen, three or four bedrooms, and bath-room. The desirability of providing lavatories and other conveniences for the public are questioned by some librarians of experience, who state that such accommodation is likely to be abused and become a nuisance. It is certain that where provided they have in some instances afterwards been closed; but, of course, they must be provided for the officials. Although in some cases more rooms may be required, these are sufficient for all ordinary purposes. If we consider the various apartments separately, the entrance hall naturally comes first. This should be as roomy as possible. In arranging an economical plan, the tendency is to reduce the hall to a minimum; but with people coming and going to and from all the rooms opening out of it, probably often stopping to chat, a small hall must at times become inconveniently crowded. It should have an outer porch, wherein, before the library itself is opened in the morning, copies of the daily papers may be posted for the benefit of men who, being out of employment, want to see the advertisements in good time. The lending library must always be on the ground floor, as near as may be to the principal entrance. Abundance of light is essential; and should top-lighting be out of the question, there must be plenty of windows, with reference to the position

of which the book-cases will have to be arranged. The room should not be less than 13ft. high (Mr. E. C. Robins thinks not less than 14ft., and no doubt he is right if the money suffices), the windows being kept up as high as possible in order to throw light over the tops of the book-cases, and to permit dwarf book-cases being placed against the wall beneath them. The old-fashioned system of arranging the books in alcoves, while very pleasant and quite adequate for college and similar libraries, is quite out of the question in free libraries, where every inch of space is wanted for some purpose. The book-cases are therefore generally arranged, so far as the lending libraries and store-rooms are concerned, in rows across the floor at right angles to the counter, to save the steps of the assistants, and to the principal windows, in order to get the light between the stacks upon the backs of all the books. As much counter-space should be provided as can be—not less than 30ft. in length—in order to allow sufficient room for the indicators and the serving-desks. Two doorways should be provided for the public as far from each other as space will permit in order to facilitate the free circulation of borrowers. With one doorway for egress and ingress also, blocks must take place on crowded occasions, such as Saturday nights. The doors here, as well as in the reading-rooms generally, must be on swing hinges, with the upper parts glazed. The reference library should be placed in the quietest part of the building, away from street noises, and “far from the madding crowd” of newspaper and novel readers. In this room the readers occupy the whole of the centre; so the books require all the wall-space, thus necessitating top lighting, which, however, is the best for other reasons. For all these reasons it may with advantage be placed on the first floor—the more so as a comparatively small number of people use it. In order to increase the storage capacity a gallery may be provided about 10ft. from the floor, which need not be more than 3ft. 6in. wide—just sufficient for a book-case against the wall and room to pass in front of it. The book-case it carries being 8ft. high, this makes the maximum height to plate 18ft. Round the room in front of the book-cases there will be a rail, and near the door a counter with desk for assistant librarian. Probably the best way of arranging the tables used by the public is to have seats upon one side

only, all the readers facing the counter. This is partly to check conversation, and partly to protect the books from mutilation or theft. Under this arrangement the tables need only be 2ft. wide, but they must be 4ft. if readers occupy both sides. Two feet in the length of the table should be allowed for each reader. Long tables are the most economical of space, but for other reasons short ones are preferable. With readers upon both sides 6ft. should be allowed between the tables; with the single arrangement 5ft. or a trifle less will suffice. The news-room, where there is another reading-room in the building, is devoted entirely to newspapers, which are placed upon upright stands just as in a club. To economise space the stands are made double to allow of readers upon each side, and they should, of course, be placed at right angles to the windows. The spacing out of the windows and size of the room should be regulated by the reading-desks. Experience shows that the desks may conveniently be placed about 6ft. 6in. or 7ft. apart from centre to centre, and, being a foot in width, this allows room for two rows of readers, and the necessary passing and repassing between. The windows may be 4ft., or even more, above the floor, as no benefit is derived from their coming lower, and looking out of them is distinctly to be discouraged. In the magazine room tables will be required, and here readers will be placed upon both sides; but, of course, not at the ends. Three feet is wide enough for these tables, and they should be at least 6ft. apart. Allowing for everything, 14sq. ft. is the minimum allowance for each reader. The position of the librarian's room needs to be carefully considered. Without being overlooked himself, he should be able to see all that goes on. It should adjoin and communicate with the lending library, and at the same time command the news-room and staircase—in fact, all the building if possible. By means of speaking-tubes, the librarian should be in communication with his assistants in all the other rooms without rising from his table. The room may possibly be used for the meetings of the commissioners, which will, of course, necessitate its being of a good size, there being always nine of these gentlemen. But it is much better to provide a separate room for them in a quiet part of the building, not too far from the librarian's room, and they like to have a long table with a

## LIBRARY FITTINGS

Illustrative of Paper on "Free Libraries" by EW Mountford FRIBA  
Reading Desk for Newspapers

separate lock-up drawer for each. A lavatory should be provided for the use of the commissioners and librarians. Of the ladies' reading-room and the boys' reading-room nothing need be said, excepting that the latter must be placed where it is constantly under the eye of some official. If a retiring-room for ladies be provided, it should lead out of their reading-room; but nearly all librarians agree that this accommodation is better dispensed with. The number and size of book stores will be regulated by the number of books the Commissioners propose that the library shall contain. For the reference library and its stores six volumes may be calculated to the lineal foot of shelving; for the lending library eight volumes to the foot. The height of cases being fixed generally at 8ft., and containing eight shelves, the requisite length for any given number of books may easily be calculated. If the library consist of two or more stories there must be a lift for books communicating with the various rooms, and there should be a private stair for the use of the officials. Nothing spoils the binding of books more than gas; therefore, until the use of the electric light becomes general, plenty of outlet ventilators should be provided by means of flues formed in the walls, or chimney shafts by openings in the roof, or the use of ventilating lights, and the burners should be kept as far above the level of the books as possible. The heating should be by means of hot water or steam, and coils are to be preferred to rows of pipes. The rooms for librarian and commissioners should have open fireplaces. Of the exterior of the building everyone will probably have his own ideas. The great thing is to have plenty of windows kept well up from the floor, and all made to open. The building should be of fire-proof construction if funds will permit, and wood-block flooring is very preferable to any other because of its noiselessness. Plate glass is desirable for the windows for the better shutting out of external sounds. The first and most important of the fittings are the book-cases. Those in the reference library are placed round the walls, being protected from the general public by a rail placed about 3ft. from them; but in the lending library and book-stores, where the public have no access to them, the cases are placed in rows across the floor, with narrow aisles between, and are made double—that is to say, with books facing both ways. These double cases are better without a central partition between the books, although sometimes a small fillet is nailed along the centre of the shelves to prevent the books in one row from actually touching those in the other. The

omission of the central partition allows of freer access of air to all the books, does away with any corners for the accumulation of dust, and facilitates the dusting or washing of the shelves. A few general principles should be borne in mind in planning the shelves of a room. First, full capacity requires that, up to 7ft. 8in. or 8ft., all wall space and both sides of all aisles be covered with book-backs. Except doors, windows and the narrow ends of double book-cases, there should be nothing in sight but the backs of books and the occasional narrow edges of the uprights. Any scheme failing this is wasting shelving capacity. Remember that every aisle is equally valuable for reaching books on either side; every face of books must have half an aisle vacant in front of it. If a face has a whole aisle, there is obvious waste in planning; 8in. more space would give an entire extra face of books. An individual shelf should not be more than 3ft. 6in. long, nor less than 8in. broad. Wood shelves are almost universally 1in. thick—that is to say, 3in. Long shelves are awkward in use, because they do not afford enough uprights to support the books properly, but we are helped to the selection of the golden mean by the experience that shelves over 3ft. 6in. long sag in the centre when full of books. The shorter the shelves the less the danger of warping, and the greater convenience of the frequent uprights which serve as book supports. The only objections are the extra cost of the uprights and the slight space lost. On the whole, 30in. is about the best length for a shelf. If you have spaces of odd lengths, the greatest length allowable is 3ft. 8in. If that length is exceeded, divide it into two—one of the standard length (30in.), and give the rest of the space to an odd short length. The reason for this is that with movable shelves the fewest possible varieties of length should be used. If all the shelves are 30in. long, any spare shelf will fit any vacant space. But if the architect will divide each wall-space into even parts, possibly twenty different lengths may be required in one building. A common error is waste of space by giving too great depth to shelves. In circulating libraries 80 per cent. of the books, as a rule, are not larger than octavo. The common octavo is only 6in. wide. Large octavos are seldom above 7in., so that a shelf 8in. deep allows liberal margin for books and a little air space. In wider shelves, which waste both money and space, the librarians are constantly annoyed by the loss of books, which are pushed into the vacancy behind the row in front. For quartos 10in. shelves are needed, for folios 16in. shelves. These are amply liberal dimensions. The best plan is to arrange shelves for books

larger than folios in separate deeper shelves, preferably below the desirable counter ledges. The best average height is 10in., which gives room for all octavos. Quarto book-shelves should be 12in. high, or they may perhaps be best put with small folios, which require 14in. The larger folios require 20in., but beyond this height the very large books may well be kept upon their sides. Of course, with the movable shelves now general it is possible to put shelves to fit each size of book exactly, but we must not overlook the fact that there is no saving whatever in reducing the shelf height, unless shelves enough are reduced to make room for one extra. Where new work is planned the height of book-cases should not be over eight standard shelves, with inch shelves and 10in. spaces between, a base of 4in., and 3in. for top cornice; this gives a total height of 8ft. from floor to top of case. The base is sometimes made 6 or 8in. high to prevent the books on lowest shelf from being accidentally knocked or injured by brooms or water in cleansing operations. This arrangement has also the advantage of relieving the strain in stooping to pick up a book from the floor level. A ledge is formed at a height of 37in. from the ground on both sides of the book-case, which is known as a counter-ledge, and is useful to librarians in reaching and returning books. The greater width of shelf below the counter-ledge provides accommodation for quarto and folio volumes. Of course counter-ledges need not be provided to every case, or they may be put upon one side only, or they may be omitted altogether, and the larger volumes placed in cases by themselves. 13 to 15ft. is a good length for a book-case—that is to say, it would consist of five lengths of shelves, the shelves being 30in. to 36in. long. Tonks's "Patent Metal Slips" and clips are the best means of supporting movable shelves, or, where these are too costly, small holes may be bored in the wooden uprights, into which are inserted brass studs to carry the shelves. If space allow, the aisles between the cases may be 5ft. or 6ft. wide; but where space is limited, as it almost invariably is, the width may be reduced as low as 30in. I should not recommend, however, making them less than 3ft. wide. Cross aisles between the ends of book-cases may be arranged of the same width as standard shelves are long, so that, if necessity arises, pins may be inserted and shelves fixed across the aisle to exactly correspond with the others. Iron shelves have been used, but wood shelving is superior to iron because it is cheaper, admits of a better finish, looks better, and is less harsh and abrading to the binding of books. When used in the British Museum, I am told the iron shelves had to be covered with leather. The

reason given for the use of iron shelving is that it is incombustible; but, unless the whole building is absolutely fireproof, it is obvious that iron shelves are useless for this purpose. In America, gaspipe frames for book-shelves are advocated by the superintendent of Buffalo Library, who claims to secure by their use—First, economy of material and lightness; second, economy of room (the divisions between the sections of shelves being of light sheet iron, no appreciable space is taken up by anything but the books themselves); third, the least possible obstruction to light; fourth, the freest circulation of air among the books, to the benefit of the bindings; fifth, cleanliness. The following remarks on the British Museum book-press, by Mr. Richard Garnett, assistant keeper of printed books, are of interest. He says:—"The introduction of a new book-press so arranged as to give additional accommodation for books, without encroaching upon the already fully occupied wall-space, is regarded as a very important event at the British Museum, where the demand for space is so constant, and the difficulty of meeting it so considerable. The merit of the first conception of the idea in England appears to belong to Mr. C. G. Virgo, till lately of the Free Library, Bradford, now curator of the Queen's Museum, Manchester. According to the best information I can procure, Mr. Virgo's device consisted in placing a shelved book cupboard before each of his presses. It was divided into two compartments, opening to right and left, thus giving access to the original press whenever wanted, and at once doubling the book accommodation, or trebling it if the shelves admitted of double rows. The means for improving this system for museum purposes were found in the peculiar construction of the new library, which consists of two stories divided by a grating, serving at once as floor for the upper and ceiling for the lower room. Instead, therefore, of a door, we proposed to place before each book-press on the lower story another book-press the facsimile of the former, provided with handles for drawing out from the wall and attached to the bars of the grating overhead by little wheels, by which, on the handles being pulled, it is found, even when full of books arranged in a double row, to run out quite easily to such a distance as to allow perfect facility of access to the press behind it. When this access is no longer required it is simply pushed back again. The indicator is an appliance of the greatest usefulness, serving to indicate what books are "in" and available for issue. It consists of a case or rack full of small holes with consecutive numbers; in these spaces are placed certain signs by which the intending borrower can tell whether the book he requires is "in" or "out." The front is glazed, the back being open to enable the assistants to make the necessary changes. The indicator stands on the lending library counter, where it is equally easy of access to the public and to the library assistants. There are different kinds of indicators in use, the two most commonly used being the Cotgreave and the Elliot. The Cotgreave consists of an iron frame fitted with as many thousand small zinc shelves as there are books to be recorded; upon each of these shelves is placed a small metallic-cased ledger, numbered alike at both ends, but in different colours—blue one end, red the other. If the blue end of the little ledger is turned towards the public the volume is available; if the red end, the book is "out." This indicator occupies a space of 4ft. by 6ft. for every 5,000 volumes. The Elliot indicator has no little books, the borrowers' ticket being placed in the numbered space when a book is issued. Its size is 3ft. square for every 1,000 volumes. There are many other systems in use; but generally they take much more counter space than the Cotgreave. The tables are best made rather heavy to prevent their being moved. In one library, where the tables are of pitch-pine, the commissioners have desired the tops to be 2in. thick, to allow of their being planed when requisite. The counters must be 2ft. wide at least, the inner side being fitted up with shelves and drawers, of which each librarian has his own views. That in the reference library may contain a row of drawers on the outer or public side, to contain the card catalogue, each drawer being 11in. or 12in. wide, some 24in. long, and 5in. deep. A thin partition divides the drawer into two compartments longitudinally, and they have double fronts, the outer ones being hinged and locked. In the inner front are two small holes, in which are placed the ends of two brass rods,

one to each compartment of drawers, which run through perforations in the cards contained in the drawers. The outer front being secured, it is impossible to withdraw the rods or remove one the cards. All counter-tops should be of polished hard wood. The catalogue case is merely a very shallow cupboard with glazed doors and a back covered with green baize or cloth, upon which are pinned lists of the titles of books which have been added to the library since the printing of the catalogue. A show case is a useful fitting in the lending library. It very much resembles the catalogue case, but is deeper and provided with shelves, upon which are arranged copies of the newest works to which the librarian wishes to call the attention of readers. It usually has the glazed front fixed, the books being put in from the back. Catalogue boards are required for displaying the catalogue of books, the leaves from which are cut out and secured to the board, two copies of each leaf being so placed to enable the public to see what books the library contains. They are fixed within the space allotted to the public in the lending library, and near the indicator for the purpose of comparison. We have now considered all the points that occur to me in connection with free public libraries. Doubtless there are others which will present themselves to your minds. My object in writing this paper has been to raise a discussion upon this important subject, which has hitherto received but little attention from architects as a body.

Mr. J. M. BRYDON, in opening the discussion, said that the views of librarians were of more importance on this subject than those of architects, but the latter could justly consider certain points in the building as well within their province. First of these was the requirement of ample provisions both of lighting and ventilation in a library; these were purely architectural questions, and unless they were properly met, and in an architectural manner, the building would be a failure. A second point to be remembered was that public libraries were necessarily managed by a very limited staff, and it was, therefore, essential to keep in view that there must be a ready passage-way for the officials through every path, and opportunity given the librarian to see and hear everything that went on. A third point to be borne in mind was the amount of space that should be allotted to each newspaper reader. Mr. Mountford had in his paper suggested 14sq. ft. per reader as the minimum allowance; but he should consider that nothing under 15sq. ft. a head ought to be allowed—if less space than this were afforded, the effect would be inconvenient crowding. The ventilation of a public library was most important. As all sorts of persons came in, the atmosphere would become almost unbearable at times—in hot weather, for instance—unless ample ventilation were provided. All windows should be as high up in the walls as possible, so as to preclude loiterers from looking out. The number of persons in a reading-room was a fluctuating quantity, and means should, therefore, be supplied for increasing or lowering the warmth or the amount of ventilation quickly and at the will of the chief librarian. One practical difficulty in furnishing a library was to get chairs that were noiseless; the grating sound made by most chairs on the wood-block floors, so usual in libraries, was unpleasant and disturbing. The reference library should undoubtedly be on the first floor, and he agreed with Mr. Mountford also that it was better to keep the books in stalls and not displayed round the walls of the room, for space was very limited. He proposed a vote of thanks to Mr. Mountford for his excellent and instructive paper, and with it he would couple the name of Mr. Appleton for having read it.

Mr. LEWIS KARSLAKE concurred with Mr. Brydon and the author that the arrangement of books round the walls of a room, although the most pleasant, was wasteful of space and less convenient to the staff.

Mr. CECIL DAVIES, chief librarian at Wandsworth Public Library, thought it was essential for architects to recollect that under the Public Libraries Acts the rate that could be levied was limited to a penny; hence it was unwise to erect a building that would cost £3,000 per annum for maintenance when only £1,000 per annum was available. In his paper Mr. Mountford mentioned that only nine library commissioners would be elected, and would require the use of a committee room. This was the case in the Metropolis; but in other towns the committee of management might consist of any

number the local authority chose to appoint. The common difficulty in planning a library was that the site was rarely rectangular; but the architect must aim primarily at giving ample light and fresh air to every department. There should be no obscure corners in the building to harbour dirt, and no portions of a room concealed by columns. The walls should be kept free from pilasters, for those at Wandsworth rendered it impossible to hang maps or prints on the walls. He did approve of the subdivision of the building into more rooms than was necessary, for it tended to create disturbances between various classes of visitors. Every portion of the room should be visible from the librarian's seat, and space should be given between all presses and rows of books to allow two librarians to pass each other. The store-room could with advantage be placed in the basement; but it should be provided with a hatch opening into the street for taking in boxes of books. As to ladies' rooms, his opinion was that they were not needed; but a separate room, under close surveillance, but not too near the entrance, should be provided for boys. If tables were reserved for ladies this was sufficient. Retiring rooms were not required. The local sanitary authority ought to make any provision of the kind outside that was deemed essential. The librarian's apartments should allow for the possibility of his being a married man with children, and should consist of at least a sitting-room, two or three bedrooms, kitchen, and scullery. Ample provision should be made for extinguishing fire should it unfortunately break out. He would appeal to architects who had designed free libraries to send plans and any particulars to the Wandsworth Free Library, where he was making a collection of such literature and its illustrations for the public benefit.

Mr. QUINN, of the Chelsea Free Library, said he concurred with the last speaker and Mr. Mountford that it was not wise to put books into the rooms, not only because they occupied much space, but because they might be stolen. Mr. Mountford was right in recommending that all windows be placed high up in walls, whereas at Chelsea they were low down and looked upon a street, any trifling movement below creating much disturbance. It was desirable in the original plans to make provision for future extension.

Mr. F. R. FARROW, in seconding the vote of thanks, said he considered it was not well to provide separate rooms for either ladies or boys, although special tables should be provided for each of those classes of readers. The multiplication of rooms wasted the space, and increased the difficulty of supervision. He should like to hear from some librarian which was the best place to put the librarian's office, whether in a separate room or where he could overlook the greater part of the building.

Mr. QUINN said two places should be provided for the librarian—a quiet office in which he could carry out his cataloguing and other clerical work, and a desk for supervision in the chief room.

Mr. A. O. COLLARD said some years since he made measured drawings of the British Museum reading-room, and could testify to the excellence of its arrangement in many details. It was practically designed, not by Sir Robert Smirke, but by his brother, Sidney Smirke, and contained, owing to successive improvements, many ingenious contrivances for economising space and saving useless labour to the staff. The presses were an excellent arrangement, and moved very easily, even when filled with books. The divisions in the reading tables and the spaces at the ends were utilised as channels, protected by wire grids, for bringing warmed fresh air into the rooms from outside. The linoleum used there was an improvement on the wood-block flooring generally employed, and was much more noiseless.

The PRESIDENT, in putting the vote of thanks, observed that the architect who planned a library should first endeavour to accommodate his books and staff and the public, and then suit his architectural style to the requirements so laid down. Too often architects who entered into competitions found almost contradictory conditions laid down, and when the design was selected and carried out, a magnificent librarian would be appointed who would declare it to be all wrong, and quite inconvenient for its purposes. While he sympathised with librarians' objections to have to keep w.c.'s and lavatories in order, he thought such places ought to be provided in the building, and not left to the sanitary authority

to find elsewhere. It was essential that the amount of space to be allotted to each reader should be definitely laid down, and he took it that in such a building natural ventilation would always need to be assisted by some one of the well-known patented appliances.

#### ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE fortnightly meeting of the Institute was held on Monday evening. Mr. Arthur Cates, vice-president, in the chair.

The deaths were announced of Mr. E. W. Stephens, of Maidstone, Fellow; and of M. Jules Louis André, of Paris, hon. corresponding member.

#### THE ROYAL GOLD MEDAL.

THE CHAIRMAN announced that the council had decided to recommend to the members on that day month, in accordance with by-law 64, the name of Mr. John Gibson as the person to be recommended to Her Majesty as the recipient of the Royal Gold Medal, for his work as an architect.

#### THE RENAISSANCE IN NORTHAMPTONSHIRE.

A paper on this subject, illustrated by numerous photographs shown as lantern slides, was given by Mr. J. Alfred Gotch, Fellow. The author referred to the influence of Italy in the middle of the 16th century on the arts and literature of England, but considered that up to the third quarter of the century the Tudor style of architecture still reigned supreme. About 1550 to 1560 the new forms were universally adopted, and the comparative quietude of the age and the great wealth of many ministers and courtiers of Elizabeth enabled them to build mansions in which to establish themselves and their posterity. Lord Burghley, Sir Christopher Hatton, and Sir Thomas Tresham were the most illustrious builders in Northamptonshire. The capricious way in which the details of the period varied in excellence was striking. Side by side, so to speak, certainly in many cases within a few yards, might be found work the most delicate and refined, and work the most coarse and clumsy; but there was no gradual growth and decadence, no possibility of assigning a date to the work by slight changes in the detail or modification of the moulding. In Northamptonshire, however, the work was of more even excellence, and, on the whole, of more intrinsic merit than that of any other district with which the author was acquainted. The capital stone which abounded in the county accounted to some extent for this exception to the general rule. Although one John Norden, in his "Delineation of Northamptonshire," in 1610, enumerated some fifty seats of noblemen and squires, there now only remained about ten for him to refer to, some having entirely disappeared, and others being completely modernised. Dingley Hall, built about 1558, still retained some notable specimens of the Early Renaissance, the work of Edward Griffin, Attorney-General to Queen Mary, who not only made use of most eccentric mouldings, but adorned his work with highly curious and illspelt inscriptions. Burghley House was next described, and letters written by workpeople at Burghley to Sir William Cecil in London were quoted, which, in common with others relating to Holdenby House, Hatfield House, and Cobham Hall, threw some light on methods of procedure connected with buildings of that era. The workpeople appeared to have applied direct to the owners for instructions; of the architect, as such, not a word was mentioned. A surveyor was here and there spoken of as going to inspect the works, but the owner apparently arranged everything and furnished the drawings, the carrying-out of which was intrusted to a foreman or clerk of works, who hired the workmen on behalf of his master. The details seemed to have been generally left to the fancy of the various artificers, who probably carried out the small scale drawings according to their own lights, though occasionally requests were met with for full details, which in some cases appeared to have been supplied by Thorpe, John Shute, Henryck, and others. Mr. Gotch then gave quotations from letters addressed to Sir William Cecil from the mason, foreman, and others at Burghley, asking how certain features or details should be carried out, and having alluded to Wothorpe, the Dower House at Burghley, built about 1600, proceeded to describe Sir Christopher Hatton's palace at

Holdenby, now entirely removed, with the exception of the entrance gate and the servants' wing. Turning next to Sir Christopher's purchase of Kirby Hall, Mr. Gotch thought there could be no doubt that the whole of the main building was built by the Staffords, and from Thorpe's plan it was known that he laid the first stone in 1570, and the work appeared to have gone on until 1575, while subsequent to 1580 various extensions took place. Fifty years later, under Inigo Jones, another and the last period of active building set in, and fortunately the judicious care of the present owner, Earl Winchelsea and Nottingham, was preventing Kirby, as far as possible, from falling into the same state as Holdenby. Reference was then made to John Thorpe's connection with the building of Kirby Hall, Burghley, and Holdenby, and also to his plans of Lyveden New Building, which was erected for Sir Thomas Tresham, who also presented to the town of Rothwell a new market-house, which, however, was never finished and had never had a roof. It was in some respects a typical Elizabethan building, and though its detail was coarse, yet it could not be denied that the whole composition had the merit of vigour and piquancy. The Triangular Lodge, Rushton Hall, and the Lyveden New Building (three interesting works by Tresham, whose works were all about the same date), Mr. Gotch considered more severe than that of Tresham's successors at Rushton, the Cokaynes. His gables were straight, many of theirs were curved, and all his architectural work was simple, elegant, and suggestive. Apthorpe Hall, one of the most striking specimens of Renaissance in the county, was next described, and its similarity to Rushton pointed out. At Lilford, a few miles from Oundle, was a fine example of the circular bay; but there was something in the stiff arrangement of the windows that told of the tame slavery to which architecture in England was about to succumb. At Drayton House was a veritable storehouse of architecture, from walls and gateways of the Edwards, to pediments and panelling of William III. One wing was dated 1684, and the exterior still proclaimed its date; the principal interest, however, lay in the vaulted cellars, which a close inspection showed to be vaulting of the days of Elizabeth. Rockingham Castle was enlarged in similar manner to Drayton House, and was well worthy of inspection. Turning to the southern part of the county, there was not much Renaissance, but Canons Ashby and Castle Ashby could not be omitted. The former was a beautiful old house presenting work of the end of the 15th, the end of the 16th, and the beginning of the 18th centuries. Castle Ashby was begun about 1583, and the bay windows of that time were easily recognised, while the fine entrance screen was the work of Inigo Jones, dated 1624. The Renaissance impressed itself not only on the great houses; every kind of building was touched, from the Palace of Holdenby to the little cottages of Brigstock and Geddington; and the author considered there were few districts in England where more suggestive features could be found for stone treatment. Having alluded to the almshouses at Weekley, Mr. Gotch, in conclusion, thought the style was the outcome of a fascinating period. All England was quivering with vitality; when Dingley was built, Spenser was six years old; when Thorpe laid the first stone of Kirby, Shakespeare was the same age; when Lilford was rising above the Nene, Ben Jonson was still alive; while, between the stoppage of Rothwell Market-house and the beginning of the Triangular Lodge at Rushton, the great Armada was shattered. It was no wonder that the architecture of the time was interesting. Into the stones of their houses the men of Elizabeth's time hewed their greatness and their simplicity.

On the motion of Mr. Wyatt Papworth, F.S.A., seconded by Mr. Ralph Neville, F.S.A., and supported by Mr. E. H. Bruton, F.S.A., of Oxford, and Messrs. S. Flint Clarkson, H. D. Appleton, J. M. Brydon, and Paul Waterhouse, a vote of thanks was cordially accorded to Mr. Gotch for his paper.

#### SOCIETY OF ENGINEERS.

THE first ordinary meeting of the Society of Engineers for the present year was held on Monday evening, February 3rd, at the Town Hall, Westminster. Mr. Jonathan R. Baillie, the President for 1889, filled the chair,

and presented the premiums of books awarded for papers read during his year of office, viz.:—The "President's Premium" to Mr. G. M. Lawford for his paper on "Fireproof Floors." The "Bessemer Premium" to Mr. Samuel Griffin for his paper on "Modern Gas Engine Practice." A "Society's Premium" to Mr. Henry Faija for his paper on "Forced Filtration of Water through Concrete," and to Mr. George R. Strachan for his paper on "The Construction and Repair of Roads."

Mr. Baillie introduced the President for the present year, Mr. Henry Adams, to the meeting, and retired from the chair receiving a hearty and unanimous vote of thanks for his services during the past year.

Mr. Adams then took the chair and proceeded to deliver his inaugural address. After thanking the members for the honour they had conferred upon him in electing him to the Presidential Chair, he briefly alluded to the satisfactory position of the Society, which now numbers 417 members of all classes, and mentioned the loss by the death of Dr. Percy, and the addition of Earl Granville, Lord Armstrong, Lord Brassey, Sir Wm. Thomson, Mr. Wm. Anderson, and Mr. Benjamin Baker to the roll of honorary members. He commented on the principal points of the papers read during the session, and described the features of interest in the works visited by the members during the vacation. The President then referred to the progress of technical education, noticing particularly the work of the Science and Art Department, and that of the City and Guilds of London Institute, and incidentally gave some particulars of the City of London College, where he has been for 21 years the Professor of Engineering. Several large bridges were described, the Forth Bridge, of course, occupying the place of honour, and references were made to many other engineering works and processes which have occupied public attention. In conclusion, attention was directed to the necessity for specialisation in the studies of engineers, the multifarious sub-divisions rendering it physically impossible for one man to thoroughly master more than one or two branches, and hence the necessity for the existence of such bodies as the Society of Engineers where experience could be freely exchanged. A final exhortation to the members to wear out rather than rust out, brought to a close a very able and interesting address.

#### MASONRY AND STONE-CUTTING.\*

By LAWRENCE HARVEY.

[TWENTY-SEVENTH LESSON.]

**CORBEL ARCHES.**—I give the name of Corbel Arches to the arches called in French "trompes"—that is, arches which carry structures projecting beyond the face of the wall. They are of three sorts; those placed within an inside angle of two walls, connecting, for instance, the parapet of a bridge with the embankment wall by a splayed angle, as in Figs. 180 and 181; those which support the projecting angle of two walls, where a splay has been formed below; those which support a semi-circular turret projecting beyond the face of a wall.

*Skew Corbel Arch in the Interior Angle of Two Battering Walls.*—In Fig. 174 we have the plan of a battering wall, of which the trace of the exterior face is the line Y A B. A triangular space, A S B, is cut out of that wall, and we are asked to cover this space by a corbel arch in order to carry a wall above.

The soffit of the corbel arch will necessarily be conical, and although the triangle to be covered is not isosceles, yet we can adopt for the soffit a cone of revolution or right cone. To do this take  $SC = SA$ , describe on diameter A C a semicircle placed in a vertical plane; let this circle be the directing line of a cone, of which S is the apex. This cone has only to be prolonged until it be cut by the face of the wall to obtain the outline of the face-arch.

We give the batter of the wall on a section, Y Z, taken on the line Y X at right angles with the wall-face. Now any point,  $d'$ , taken on the base circle of the cone, will have its plan,  $d$ , on the line A C; and on the section (Fig. 175) its elevation,  $d'$ , will be at the same height above the ground-line Y X as  $d'$  (Fig. 174) was above the ground-line A C.  $S'd'$  will be the projection on the section of a generator of the cone; that generator prolonged cuts the wall-face in D' (Fig. 175), the plan of which is D (Fig. 174) on the

generator  $Sd$ . Similarly, a series of points are found which give the intersection of the wall-face by the soffit of the arch.

Instead of drawing the elevation of the raking wall-face, we turn down the wall-face itself round its horizontal trace, so as to get the real shape and dimensions of what is delineated on its surface. In doing this the points  $(DD')$ ,  $(EE')$ , describe arcs of circles, of which the radii are  $D'Y$ ,  $E'Y$  . . . the planes of these circles being at right angles with the hinge of rotation  $AB$ . This gives us  $D'E'$ , . . . the real shape of the face-arch is, therefore, the curve  $AE'D'B$  (Fig. 176).

The tangent to any point,  $D'$ , of this curve is the intersection of the plane of the wall-face with the plane tangent to the cone in that point. To find this intersection, draw the trace of the tangent plane to  $d'$  on the base of the cone; where this trace cuts the line  $AC$  the horizontal trace of that plane will pass, another point being the apex,  $S$ . Then draw the horizontal trace, and through the point where it cuts the line,  $YB$ , draw a line to the point,  $D'$ , on the curve; this will be the tangent required.

In the point  $A$ , the plane tangent to the cone is vertical, its intersection with the wall-face is  $AS$  on plan, and  $YZ$  on the section (Fig. 175). To draw it on the turned-down wall-face (Fig. 176) take a point,  $x$ , on plan, and  $Z$  on elevation, and draw its position in Fig. 176;  $Ax'$  (Fig. 176) is the tangent to  $A$ . The tangent to  $B$  is found in the same way. These two tangents must necessarily intersect one another on the vertical drawn from  $S$ .

To find the highest point of the curve, the one where the tangent is horizontal, note that the trace of the tangent plane will pass through  $S$ , and be parallel to the ground line,  $AB$ . Draw that trace till it cut  $AC$ , and from the point of section draw a tangent to the circular base of the cone; this will give  $u'$ , on the generator of which is  $U$ , the highest point of the face-curve. As the point of section may be too far, we need only find the mid point,  $\omega$ , which we would use to draw the tangent according to Fig. 182. This would give us the point,  $U$ , on the circle.

A still shorter method of finding the highest point of the curve is based on the following property of conic curves; the two tangents,  $AS$  and  $BS$ , taken through the extremities of the chord,  $AB$ , must intersect one another on the diameter conjugate to  $AB$ ; and the tangent in that point of the curve will be parallel to  $AB$ . Therefore, join  $S$  to the mid-point,  $W$ , of  $AB$ , and  $SW$  will be the diameter which will contain the point,  $U$ .

The bed-joints are taken through the centre line,  $SOI$ ; but the joint lines of the arch must neither be equidistant on the face-arch, nor on the circular section of the cone. In the first case the soffits of the arch stones would be of strikingly different widths. In the second case the joints on the face-arch would be too irregular. The best way is to draw both systems of division, and then take intermediate points which give a sightable division. Then the arrises of the bed-joints on the face-arch will be  $ID'H'$ ,  $IE'F'$ , . . . which are stopped by the horizontal joints of the wall. The face mould of one of these arch-stones is, therefore,  $D'E'F'G'H'$  (Fig. 176), from which the horizontal projection can be drawn by taking down perpendiculars to  $AB$  until they meet the lines  $IE$  and  $ID$ . It will be safer to bring the points back by arcs of circles on the section,  $XY$ , and then deduce from this the plans of the points.

*The Eye of the Corbel Arch.*—If the bed-joints were carried back to the apex of the cone, they would present an unsafe feather-edge in that point. It is usual to stop them at a distance of 8in. to 10in. from the apex, and form the remainder of the vault out of one stone; this is the eye of the arch. To make the joint-line of the eye parallel to the face-arch, cut the conical soffit by a plane  $zyab$  parallel to the wall-face. On Fig. 175 the generators of the cone are cut in  $n''$ ,  $m''$ , . . . of which the planes are  $n$ ,  $m$ , . . . This gives the projection  $anmb$  as the joint line of the eye where the soffits of all the archstones will stop. The surface of the joint itself must be normal to the soffit of the arch. Therefore, find the normal in the point  $m$  by turning down the generator  $sm$  on  $SB$ ; the point  $m$  will then come to  $m''$ . The normal  $m''L$  will be the turned-down normal, and as  $L$  is on the centre line, the normal itself will be projected in  $Lm$ . Similarly, normals through any number of points can

be found, and thus the skew surface of the eye-joint will be defined.

To complete the eye-stone we must let it be comprised from front to back between the vertical planes  $ab$  and  $VP$  (without yet determining its lateral faces), and then find the intersection of the top plane of the stone with the skew surface of the eye-joint. Use as elevation plane the circular section of the arch, for on that plane the normals are projected on the radii of the circle. Let the upper face of the eye-stone be on elevation the line  $R'M'$ ; then the intersections of that line with the radii of the circle give us the elevations of points of the intersection required, from which we deduce their horizontal projections on the plans of the normals, and draw the curve  $MNR$ . In case the projecting lines met at too sharp an angle to be able to define exactly the point, as is the case for the point  $N$ , then turn down  $N'$  round centre line  $OS$ , and get  $N''$  on the turned-down normal  $Kn''$ ; then turn back to  $N$  on  $Kn$ .

To avoid a break in the joints of the arch-stones where they come in contact with the eye, make each of the side arrises of the eye coincide with a bed-joint. Therefore adopt  $MP$  and  $RV$ , drawn parallel to the centre line  $OS$ , as lateral faces of the eye. To finish the eye-stone we have to find the intersection of these lateral faces with the skew joint of the eye. The normals  $aa$  and  $rr$  are cut by the lateral face in the points  $a$  and  $R$ , the last of which, when turned down on the mould, comes to  $R_2$ . Constructing several intermediary normals, and finding their intersections, we obtain the lateral mould  $aR_2V_2V$ . Similarly we obtain the other lateral mould  $P\beta M_2P_2$ ; lastly, to cut the eye-stone, the real shape of the joint line  $arnmb$  is required, for which turn down plane  $zyab$  round  $ab$ , as we have done for the curve  $AE'D'B$ .

Now, to cut the eye-stone, form the prism which contains it; then cut off the front plane with the help of a bevel of angle,  $zyX$ . On that face mark the outline of the curve  $arnmb$  (Fig. 177). On the upper plane place the mould  $V_2RNM_2P$ , and on the lateral sides the moulds  $V_2aR_2V_2$  and  $P\beta M_2P_2$ . Then work the skew surface of the eye-joint by means of a straight edge guided by the outlines drawn and by guiding points, such as  $Rr$ ,  $Nn$ ,  $Mm$ , . . . marked on the moulds. On the lower plane place the triangle,  $aSB$ , taken from the plan (Fig. 174), and work the conical soffit with a straight edge.\*

*Bed-moulds of the Arch-stones.*—The arch-stones abut partly on the skew surface of the eye-joint and partly on the upper plane or the side planes of the eye. The bed-joints will, therefore, be finished by portions of normals to the soffit, and by straight lines parallel to the centre line,  $SO$ . For instance, for the arch-stone  $DEFGH'$  on the wall face, the projections of the beds will be  $FEnNQfF$  and  $HDmMPH$ . To get the moulds thereof turn them down round,  $SO$ , and note: *firstly*, that each point describes a circle perpendicular to the hinge,  $SO$ ; *secondly*, that  $K$  and  $L$ , where the normals cut the hinge, remain unmoved; *thirdly*, that the lines  $IEF'$  and  $IDH'$  will always pass through the point  $I$ , and have their true lengths shown in the lines  $IE'F'$  and  $ID'H'$  (Fig. 176). The moulds are then  $F''E''N''Q''f''F''$  and  $H''D''m''M''P''h''H''$ .

*Soffit Operation Planes.*—In cutting the arch-stones, to avoid a great loss of material, we must begin by working an operation plane on the soffit of each stone, and start from this plane to work the bed-joints, and the wall-face by means of bevels. Instead of developing the cone which forms the soffit of the arch, develop the pyramid formed by planes stretching from joint to joint. The easiest way to produce this development is to use the chords of the divisions to the base circle. Take, therefore,  $AS$  (Fig. 174) as radius, and draw a circle (Fig. 178), on which carry the lengths of the chords  $Cd$ ,  $de'$ , . . . (Fig. 174); connect these points with the centre  $S$  (Fig. 178), and you have the direction of the joint-lines. On these lines carry their real lengths  $SB$ ,  $SD''$ ,  $SE''$ , . . . equal to the lengths given by the bed-moulds (Fig. 174); then connect the points  $B$ ,  $D''$ ,  $E''$ , . . . by straight lines, which will be found to be equal to the chords drawn on Fig. 176. From the joint-lines will have to be left out the lengths  $Sb$ ,  $Sd''$ ,  $Se''$ , . . . which belong to the soffit of the eye.

\* In our diagram the lines relative to the eye are shown full, as if the eye were drawn alone, uncovered by the arch-stones.

In order to work the skew surface of the joint where the arch-stone abuts upon the eye, we must get the intersection of the soffit operation plane with that skew surface. To do this, cut both the operation plane and the cone by a plane passing through the centre line and through a point  $\gamma'$  taken anywhere on the chord  $d'e'$  (Fig. 174). The section of the operation plane will be  $S\gamma$ , and of the cone  $S\delta$ , which meets the curve of the eye in  $\epsilon$ . Produce the normal  $\epsilon\lambda$ ; the point  $\phi$  where it cuts  $S\gamma$  is a point of the intersection  $n$ ,  $\phi$ ,  $m$  of the operation plane with the eye-joint.

To draw this curve on the operation plane (Fig. 178), turn down the line  $S\gamma$  to  $S\gamma'$  (Fig. 174); then the turned-down normal  $\lambda\epsilon''$  will cut  $S\gamma'$  at a distance  $S\phi'$ , which carry on the line  $S\gamma'$  (Fig. 178), by which you obtain one point of the curve  $n''\phi''m''$  required. In practice only these last operations are delineated, and the projection  $n\phi m$  is not drawn.

To work the wall-face of the stone with a bevel, the angle comprised between the soffit operation plane and the wall-face must be found. These two planes and that of the bed-joint form a triangular pyramid, of which the apex is the point  $E$ , and of which the angles comprised between the arrises are known; therefore we can find the angle comprised between the planes. In Fig. 178 draw angle  $D'E''F'$  equal to the angle  $D'E'F'$  of Fig. 176, and another angle  $SE''F''$  equal to the same angle on the bed-mould. When these triangles turn round their respective sides  $SE''$  and  $E''D''$ , the points  $F''$  and  $F'$  meet on a vertical over  $\omega$ ; the vertical over  $\omega$  forms with  $\rho\omega$  a rectangular triangle, of which the hypotenuse is equal to  $\rho F'$ ; this triangle, turned down round the line  $\pi\rho\omega$ , gives us the triangle  $\rho\omega\zeta$ , and the angle of the bevel is therefore  $\zeta\rho\pi$ .

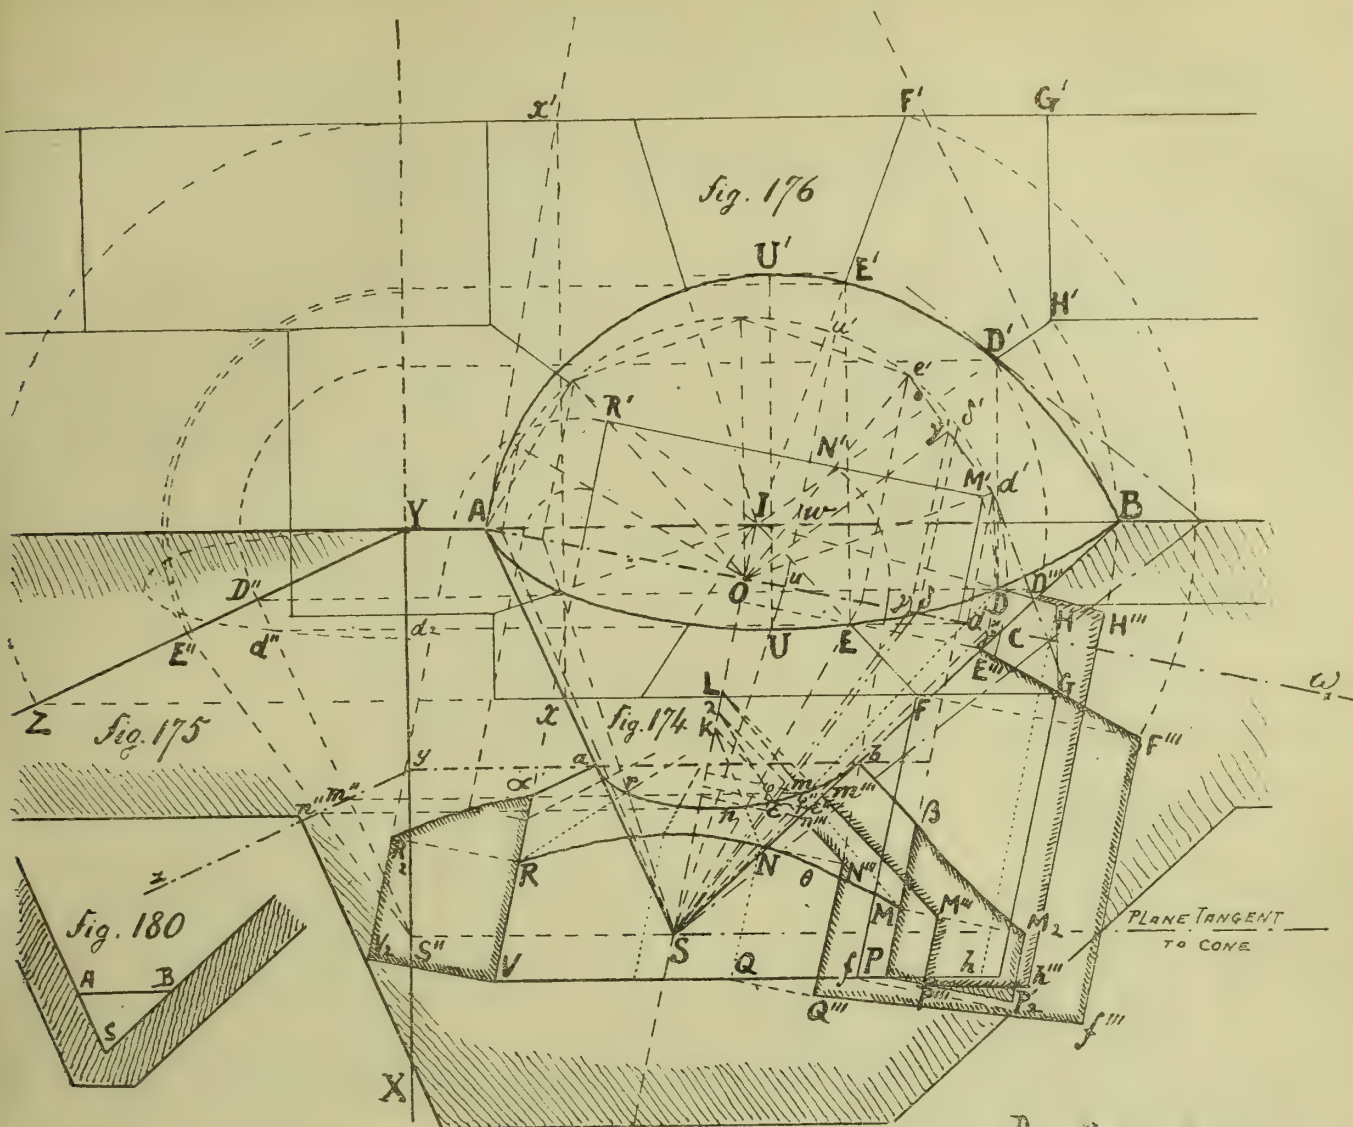

*To Work the Stone* (Fig. 179),  $D'E'F'G'H'$  on face, select a stone that will comprise it, which must be judged from the projections on Figs. 174 and 175. Dress the face of the soffit operation plane, and with the help of the mould (Fig. 178) draw thereon the outline  $Dm\phi nE\gamma D$  (Fig. 179). Then with a bevel of angle  $\pi\rho\zeta$  (Fig. 178), work the wall-face of the stone, one branch of the bevel sliding on the operation plane, while the other branch is held normal to the chord  $D\gamma E$ . On that plane of the wall-face draw the outline  $DEFGH'$ ; then work the plane of the upper bed-joint through the lines  $En$  and  $EF$  marked on the stone, and draw thereon the mould  $EnNQfF$ . The bed-joint might also be dressed with the help of a bevel equal to the angle comprised between it and the soffit operation plane, an angle easily found in Fig. 178. The lower joint is worked in the same way as the upper joint, and its mould is also drawn thereon.

Now, guided by the lines of the bed-joints, work the plane  $PM\theta NQ$  gradually until the template  $\theta N$ , taken from Fig. 174, can be placed thereon. Then work the skew surface  $Mm\phi nN$  with a straight edge, guided by the curve  $M\theta N$  and  $m\phi n$ , and passing by the connecting-points  $M$  and  $m$ ,  $\theta$  and  $\phi$ ,  $N$  and  $n$ , taken from Fig. 174. On this skew surface delineate the curve  $m\epsilon n$  by carrying on each generator  $\phi\theta$  the length  $\phi\epsilon$  equal to  $\phi'\epsilon'$  of Fig. 174. Lastly, excavate the conical soffit of the stone guided by the lines  $m\epsilon n$  and  $D\delta E$ , keeping the straight edge upon the corresponding points  $D$  and  $m$ ,  $\delta$  and  $\epsilon$ ,  $E$  and  $n$ .

The foundation stone was laid at West Hartlepool, on Friday, of a new Baptist chapel to be erected on the corner site of Tower and Archer streets, from designs by Mr. J. Garry, architect, of that town, by Mr. Davison, contractor, Stockton-on-Tees. The Tower-street frontage will be 41ft., and that in Archer-street 64ft., and it will be in the Gothic style of architecture, and will seat 264 on the ground floor and 250 in the galleries. The building will cost £1,800, and will be supplemented by additions costing £400 more.

The first of the new branch libraries and reading-rooms to be established in Liverpool was opened on Jan. 30. The new building stands on a portion of the recreation ground in Kensington—a rapidly-growing neighbourhood—and has cost £3,000. It occupies an area of 400 square yards, and comprises a reading-room, 38ft. by 32ft., a lending-library, librarian's rooms, &c., the plan being so arranged that the librarian from his desk can control both the reading and lending departments. The style chosen by Mr. Thomas Sheldermine, jun., the corporation architect and surveyor, is stated to be German Renaissance. The contractor was Mr. Edmund Gabbett, of Oaks-street, Liverpool.

CONTEMPORARY BRITISH ARCHITECTS.—"A HARVEST FESTIVAL."—THE DURHAM PASTORAL STAFF.—BOARD SCHOOLS AT BECKENHAM.—ST. MARGARET'S CHURCH, ABERDEEN.  
—NEW CREMATORIA AT PARIS AND ZURICH.

## OUR LITHOGRAPHIC ILLUSTRATIONS.

CONTEMPORARY BRITISH ARCHITECTS.

SEE description on page 221.

## "THE HARVEST FESTIVAL."

This design for the decoration of a public building, by Miss Gertrude Demain Hammond, was awarded the Royal Academy Prize, as we stated last week, when giving her cartoon of the central group. The general composition now reproduced from the artist's water-colour drawing, will show how these figures come in the design. Mr. Akerman, though working from a painting in which yellows and blues predominated, has very successfully rendered the several values in the picture. We name this so that other contributors may know that we are now able to reproduce almost any style of drawing, whether in colour or not, provided it is clearly defined and properly delineated.

## DURHAM PASTORAL STAFF.

The pastoral staff of which we give an illustration was presented last October (in an incomplete state) to the late Lord Bishop of Durham, in Bishop Cosin's library, by the Earl of Durham. The work is of silver gilt, jewelled, with enamelled heraldry, and is now just finished. It is executed by Messrs. Carrington and Co., from a design by Mr. William Searle Hicks, of the firm of Hicks and Charlewood, architects, Newcastle-on-Tyne. The figures are modelled by Mr. G. W. Milburn, the sculptor, of York and London, and they represent on the obverse of crook the Crucifixion, the Blessed Virgin Mary, and St. John; and on the reverse the Good Shepherd, with SS. Peter and James. Below the crook is the "Agnus Dei," with the inscription "Et ego cognosco eas et sequuntur me." Round the main tower are the figures of SS. Cuthbert, Aidan, Oswald, Bede, Hilda, and Chad. The heraldry of the diocese of Durham and Bishop Lightfoot are on the knop at the base of the crook. Below the jewelled knop is a richly-ornamented hexagonal portion, bearing the words of our Lord's pastoral charge to St. Peter—"Pasce agnos meos," "Pasce agnos meos," "Pasce oves meos."

## THE ARTHUR-ROAD SCHOOLS, FOR THE BECKENHAM SCHOOL BOARD, KENT.

This school was won by Mr. John Ladds in a limited competition, for which Mr. E. R. Robson, the architect to the Educational Department, acted as referee. Accommodation is provided for 240 boys, 240 girls, and 320 infants, and the schools are capable of enlargement to accommodate 360 boys, 360 girls, and 480 infants. There is also a caretaker's house. In consequence of this proposed future enlargement, it was

thought advisable to arrange the schools in three separate buildings, or rather two, the boys and girls being connected in one place although they have no internal communication. The materials to be used are stock bricks and Broseley tile roofs. The class rooms will all be well lighted, the floors will be of wood blocks, and the heating and ventilating will be by means of Mr. D. O. Boyd's patent ventilating grates. The contractors for these works, which have just been started, are Messrs. Willmott and Sons, of Hitchin.

## THE AYLESBURY-ROAD SCHOOLS, FOR THE BROMLEY SCHOOL BOARD, KENT.

This school will at first provide for 250 boys only; but the Board contemplate a further enlargement by the addition of the same number of girls and infants respectively, and in the recent limited competition architects had to show in what way they proposed to make this addition. A caretaker's residence was also included in the competition. Mr. R. Norman Shaw, R.A., acted as referee. The arrangement of the school, which was also designed by Mr. John Ladds, who gained the first premium in the competition, is simple and compact, and the design plain and unornamental. The buildings will be of stock bricks throughout, with large, plain windows giving plenty of light, the lower portion fitted with double-hung sashes, and the upper part casements, hinged to the transom to fall inwards, and closed by means of Leggett and Co.'s patent casement openers. The floors will be of wood blocks throughout; the roofs covered with slates, and the gables rough-cast. The Board have accepted the tender of Mr. Thos. Crossley, of Bromley, for the erection of the school, subject to the approval of the Education Department, and the works will be put in hand shortly.

## ST. MARGARET'S CHURCH, ABERDEEN.

This drawing of the church of St. Margaret of Scotland, Aberdeen, shows the interior as it will be when the proposed alterations and additions are carried out. The view is taken from the western chapel of St. Nicholas, which was completed and consecrated last October. The nave and chancel are at present only half the height shown in the drawing and are of a temporary character, having been designed only to serve as a chapel-school, though eventually to be consecrated as a parochial church. While from the narrowness of the site the building must still retain its chapel form, it is proposed to give it a dignified proportion and character by means of internal buttresses carrying a vaulted roof, and, at the same time to extend it to its furthest limits at the East end. Messrs. Bucknall and Comper are the architects, and the drawing given was exhibited at the Royal Academy last year.

## CHIPS.

Further enterprise in anticipation of the development of the London and South-Western Railway Company's works at Bishopstoke, Hants, has shown itself by the purchase of the Chickenhall Estate, a freehold property of some 115 acres, situate within a half-mile of Eastleigh Station, till recently familiar to South-Western passengers as "Bishopstoke Junction," and in close proximity to the new sheds and workshops. The property has been acquired with the intention of development as a "Model labourers' dwelling estate," allowing to each house, to be built either separately or in pairs, large gardens.

The annual meeting of the Cambrian Archaeological Association will take place next August at Holywell in Flintshire, under the presidency of Lord Mostyn.

The new chapel erected at Fulham Union Workhouse has been dedicated by the Bishop of London. The structure is Gothic in style, was designed by Sir Arthur W. Blomfield, A.R.A., and cost about £4,000.

Professor Stuart, M.P., has resigned the Professorship of Mechanism and Applied Mechanics, which he has held in Cambridge University since 1875.

Three stained-glass windows will be placed in Manchester Cathedral in the course of a few weeks. Two will be placed in the extreme west of the north wall, beside the porch recently completed, and the third will be erected in Brown's Chapel. The old scholars of the Manchester Grammar School propose to erect another window to the memory of Hugh Oldham, the founder of the school. The lowering of the entire floor of the Cathedral will be proceeded with, in order to expose the exquisitely-carved plinths of the pillars supporting the arcades of the nave.

## NEW CREMATORIA AT PARIS AND ZURICH.

THE movement in favour of this system of dealing with the remains of the dead grows daily, and continues to interest a very large section of the community both in Europe and America; indeed, in New York an endeavour is being made just now to erect a new mausoleum or Campo Santo in connection with crematoria on a large scale, and the company promoting the scheme has for its mission the disposal of the dead by desiccation, which, in plain terms (not to use the word fire), is the art of preventing putrefaction by forcing over and around the body a continuous current of dry air, the agency of evaporation. The ancient Peruvians, the Colchians, and the Tartars, as well as the Ethiopians practised desiccation by suspending their dead in the sun, or by drying them on an elevated spot. In India and China the method of burning is still in vogue. The Capuchin Monks of Palermo are said to have adopted less crude methods by baking their dead in ovens constructed in the catacombs there. Modern science has developed the ancient Roman idea, and special edifices adapted to the process are being built in many places. We give an illustration of two recent examples to-day. The crematorium from the central cemetery at Zurich is built on the plan advocated and invented by M. Emile Bourry, engineer, of Saint Gall. There is nothing in the external appearance of the structure to denote its purpose, as will be seen by the view given herewith; but the interior sketch shows the furnace top and the sliding table, with a coffin in position ready to be placed in the desiccating chamber. The door beyond, to the left of the drawing, leads to a waiting-room or vestry. The chimney from the furnace is hardly visible on the outside. The Paris building was designed by M. Jean Formigé, architect, of Rue Coëflogon, and as the plan, elevation, and section will explain, seems far more suitable, architecturally, for the purpose for which it is intended. There are three crematoria placed in chapel-like recesses at the end, and separated from the main part by an aisle or lobby. The central compartment of the three has an apsidal end, and the light is admitted by windows entering through the barrel vault. A double dome surmounts the main building, and the external treatment, as well as the inside, seems cleverly designed. We are indebted to "La Construction Moderne" for these drawings, and those of Zurich were borrowed from the *Schweizerische Bauzeitung*.

## COMPETITIONS.

HULL.—At a meeting of the directors of the York Union Bank, Limited, held in York, the plans of Messrs. Smith and Brodrick, architects, of Hull and Goole, were selected from the designs submitted in a limited competition for the new branch banking premises to be erected at Hull. The building will be stone, and in the Flemish Renaissance style, and will be erected at the corner of Lowgate and Bowlalley-lane. The ground floor will be occupied by the banking premises of the York Union Bank, above which will be offices for letting purposes. It is proposed to commence the building forthwith.

WESTON-SUPER-MARE.—Local and other architects were invited to submit plans in competition for a church to seat 800 persons which it is proposed to build in the Locking-road (opposite the Potteries). Several designs were sent in, and that under nom de plume "Crux," by Mr. S. J. Wilde, architect, of Weston-super-Mare, was unanimously selected. The accepted design is in the Early English style of architecture.

At Patrick Dean of Guild Court the plans have been passed of a new orphanage which is to be erected by the trustees of the Glasgow Institution for Orphan and Destitute Girls, on ground at Whiteinch, west of Victoria Park. The building will have a frontage of about 150ft. The main portion, which will be three stories in height, will have a frontage of 90ft. to a new street, and will extend westwards a distance of 80ft. The estimated cost is over £5,000.

The opening services of the new Wesleyan chapel situated in Ogden-lane, Higher Openshaw, Manchester, were held on Friday. The new building is in the Classic style, and is built in red-faced stock bricks with stone dressings. The cost has been about £2,700.

## WAYSIDE NOTES.

IT was only to be expected that your article on "Wholesale Contracts" would call forth some correspondence; and it will not be surprising if very many hasten to give their opinions on the subject in your columns. Naturally enough, the builder and contractor regards any adverse criticism of the recognised system of contracting, as only an attempt to take bread out of his mouth, which, however, no one really wants to do. Under whatsoever arrangement modern buildings are carried out from architects' designs, there will be work and employment for all heretofore engaged. It is moreover unnecessary that any heated argument should take place in any controversy there may be on this subject, for write and talk as one may, the existing methods will continue in vogue. Progress in these matters is so slow that the utmost one can expect is that here and there endeavours may be made to work on the system advocated—namely, that where the first care of all shall be the work in hand, and not the profit and loss account.

I think that both your correspondents, who last week gave the results of their experience, in a measure failed to take the proper view of your position. No one imagines that *sub-contracts* are going to remedy the shortcomings inherent to the *wholesale contract*. The evils of sub-letting were realised by architects years and years ago, as the anxiety about the inclusion of the "no sub-contract" clause in specification goes to prove. If the question is between contracts and sub-contracts, I beg to retire altogether from its discussion. The system I have in my own mind is that where a master builder is engaged to superintend the works, the purchase of materials, the workmen, and everything to do with the building—a system akin to that employed in days gone by—the system upon which Monsieur Paul and the "grand cousin" erected the château for "madame," and one daily employed with success in England, though more often in other countries. We want the old *master builder*, and if a few of our contractors, instead of dragging out a life of chronic anxiety and worry to make both ends meet, and periodically causing other men to suffer through their bankruptcy, would boldly make a speciality of the trade of a master-builder, they would ultimately find it to their benefit. Such men would have to possess all the business qualities of the genuine contractor, and the knowledge of trades, manufactures, and the manners and customs of the British workman acquired by a competent foreman, together with the attributes of the clerk-of-works. Who will say that, in these days of extensive buildings involving heavy responsibility in their erection, men of this stamp would not find constant and lucrative employment, and lead a happier life than that of erecting buildings by contract at ruination prices? I make bold to assert that those who had the pluck to commence, immediately, systematic and long-continued advertising of themselves as *master-builders*, would in time and by steadfast integrity gain for themselves a special line of business. In days to come, plenty of private individuals and civic corporations to whom price is a secondary question to that of obtaining first-class work, will be on the look-out for men with a reputation for carrying out works on the system advocated. Only the advertisers must be all I have suggested as regards qualifications, or their services will be dispensed with at the end of the first week, and six days be the span of their careers as master builders of the old type. I may be mistaken, but there seems an idea here of which builders, contractors, and clerks of works might take advantage.

The Society of Engineers listened to the address of their new president early this week. Mr. Henry Adams, the indefatigable and energetic, has the honour of holding the presidential post this year, and under his auspices the society should do well.

Another attempt has been made to jog the memory of the County Council with regard to the proposed Blackwall Tunnel, the people of East Greenwich having met together on Monday evening last and done a good deal of talking. I have said before that wonder and reverent regard for great constructional undertakings is becoming a thing of the past, and that even the infant of

the 20th century will regard with positive disdain the marvels of the "puff-puff," and other triumphs of science and engineering. At the East Greenwich meeting, Mr. B. Mitchell, the chairman, said that, "while a Channel bridge and a Channel tunnel were talked of, it seemed ridiculous to say it was impossible to construct a tunnel under a narrow stream." The "narrow stream" is to be observed. When Mr. Brunel was at work beneath old Father Thames, a *mighty river*, was doubtless the only wear. Now the Thames is a "narrow stream." And the cause of this disdainful view of the river is the hypothetical bridge and tunnel which are to join England with the Continent, according to some, but which, according to reasonable persons, will never be constructed. I dislike a want of reverence for things created by God or man: it evidences littleness and conceit.

I cannot, however, understand where the idea about the impossibility of constructing the proposed Blackwall tunnel came from. It has evidently grievously affected the inhabitants of the district that expects to be benefited by the construction of the subway. That it would be made only at an enormous expense and with considerable risk one may imagine; and that it is not a desirable undertaking we may also well believe. It would be rather interesting to know exactly the history of happenings that have led the inhabitants of East London to make so much of the "impossibility" incident. It appears to me to be of the nature of a myth. The Board of Works were fully alive to the arduous nature of the undertaking; but it is difficult to imagine anyone in authority to have stated it to be an impossibility. The County Council, perchance, deem it best to go cautiously to work because of the outlay involved, and, in so doing, one cannot but think that they are well advised.

A rather unusual incident has occurred in connection with the competition for the Swedish Houses of Parliament at Stockholm. In addition to giving liberal premiums, we learn that the authorities have thought fit to purchase, for the sum of 1,000 kronor each, two other of the designs submitted in the competition. This is honest and manly of the Swedish Government. They want to include some features in the ultimate design that these two competitors have schemed, and to that end they pay 2,000 kronor. We are not all so honest or liberal. If some people want to do the same thing they simply crib and plagiarise with an admirable coolness and "face." I recommend to the notice of competition inaugurators the action of the Swedish Government. In the past history of architectural competition we have too often seen cases where the whole affair is a mere fiasco, prearranged so that the largest amount of ideas may be obtained at the lowest possible cost—a veritable process of architects' brain-sucking.

The County Council are unfortunate in the matter of engineers. What with death and resignation, it must be a constant source of anxiety and trouble to fill the post. At Tuesday's meeting at the Guildhall, Sir John Lubbock announced that Mr. Dunscombe, the Council's engineer, had tendered his resignation on account of ill-health. I am inclined to think that the burden of responsibility must lie heavy on those holding this berth, and that only men of iron constitution are fitted to discharge its duties. Unfortunately, the engineer of to-day is a man of figures and mathematical calculations, the attainment of proficiency in which means, generally, health destroyed, mental application and study in early manhood. Yet no one can hope to attain great success and a great name as an engineer who has not physical stamina. As a type for an engineer I would take Sir Frederick Bramwell, whose remarkably hale and hearty condition in advanced years bespeaks the care bestowed through life on matters of health. If only students of arts and sciences would early recognise the futility of the *mens sana*, unless it be really in *corpore sano*, it would be well for the life of the individual and the nation. I cannot picture to myself a great engineer unless he be a man of fine physique, with bodily powers at all times equal to those of the mind. This digression may or may not be pertinent to the subject that caused me to reflect. Anyhow, I am extremely sorry for Mr. Dunscombe that he should find it necessary to resign his position, and trust

that by persevering the County Council may at last get an engineer who will become an old servant.

Another correspondent has felt himself bounden to contribute to the daily press a protest against the action of authorities in leaving the stones of the Burlington House Colonnade to go to rack and ruin. "In a swamp at a remote corner of Battersea Park." We shall all sympathise with "S. H. B." in his letter to the *Standard* of the 5th. But I hear from friends who have lately explored the region of this howling wilderness of desolation, that the stones are quite spoilt beyond any hope of piecing them together again. It is some years since I amused myself by examining these curious and once beautiful relics, but can well believe, remembering their then condition, that gaming youngsters and wantonly destructive young urchins have done their worst.

It has been suggested, as within the bounds of possibility, that the cholera, lately prevalent in the trade routes of the East, may follow the influenza in the warmer weather. What price will our system of sewer-ventilating into streets exact from us if this takes place? Day and night, night and day, the germs of the pestilence would be issuing from the myriads of street ventilators and spreading disease broadcast, even as they do now with other scourges that are the punishment of dirt and filth. Considering what this means in a population of four millions, one is inclined to think that the antiseptic property of London fog is our only safeguard. If the vast clouds of particles of free carbon are to be some day swept away by municipal reform, simultaneously the sewer-ventilators must be sealed, and the sewer air passed over furnace fires, or the Metropolis will be decimated by the first serious pestilence that creeps in from the Eastern countries.

GOTH.

## CHIPS.

The Bishop of Plymouth opened on Thursday in last week the chapel built in the grounds of St. Vincent's Orphanage for Boys, Teignmouth-road, Torquay. The new chapel is a small, plain, brick building, with stained and varnished boarding inside, and three small stained-glass windows over the altar; it provides accommodation for a hundred worshippers. It has been erected, from the designs of the Bishop, by Mr. Lethbridge, of Plymouth.

The Court of Common Council discussed at their last meeting a motion by Mr. Treloar that it be referred to the Library Committee to consider the desirability of opening the Guildhall Library, Museum, and Art Gallery on some part of Sundays, and to report their opinion thereon to the Court. After a long debate, in which the arguments in favour of and against the opening of museums on Sundays were advanced, the "previous question" was carried by 83 votes against 43.

The Duke of Westminster has undertaken the expense, estimated at over £1,000, of putting stained glass in the windows of the fine collegiate church of St. John's, Chester.

Personalty to the value of more than £115,000 was left by the late Mr. James Duneau Doulton, whose will has just been proved by Sir Henry Doulton, the brother, Ronald Duncan Doulton, the nephew, and James Doulton, the cousin, the executors. After making various bequests to the members of his family, the testator directs his executors to distribute £1,500 among the managers, clerks, travellers, and foremen in the employ of Messrs. Doulton and Co.

Goole parish church, after undergoing restoration, was reopened on Tuesday. A new peal of bells, a new organ, vestries, choir stalls, altar rails, and silver Communion service have been provided at a cost of over £2,000. The new vestries were designed by Mr. H. B. Thorp, of Goole; while Messrs. Smith and Broderick, of Hull and Goole, were the architects for the other improvements. Mr. William Denison, of Normanton, was the contractor for the structural alterations and extensions.

The Waterworks Committee of the Cardiff town council has come to an arrangement with Mr. Jones, the former contractor of the Cantref Reservoir, as to the moneys due to him. Mr. Jones's original claim was £56,000, which was brought down to £27,513, and he has now agreed to accept £22,320 in settlement.

The church of St. John the Evangelist, Breck-road, Everton, erected through the munificence of Mrs. Turner, of Dingle Head, to the memory of the late Mr. Charles Groves, was consecrated by the Bishop of Liverpool yesterday afternoon.

## CONTEMPORARY BRITISH ARCHITECTS.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

CONTINUING our gallery of photographs, we print to-day our fifth sheet of portraits, with each of which a few particulars of the work done by the several architects represented are given.

Mr. John McKean Brydon, F.R.I.B.A., was a pupil of Messrs. Hay, of Liverpool. He served afterwards in the offices of Mr. David Bryce, Edinburgh; Mr. Campbell Douglas, Glasgow; and Messrs. Nesfield and Shaw, in London. Among his principal works are the Mansion Houses of Lewins, in Kent, with its home farm; Pickhurst, in Surrey; additions to Holmwood, in Kent, for Lord Bramwell, and Summerfield, near Roehampton; also two houses at Haverstock Hill; house at Airlie-gardens, Campden Hill; house and studio, St. John's Wood, for M. Jas. Tissot, the French painter, and since rebuilt by Mr. Alma-Tadema; houses at Rustington, in Sussex, and Hatfield Broad Oak, in Essex (now building); St. Peter's Hospital, Covent Garden, opened by the late Duke of Albany in 1882; the New Hospital for Women, Euston-road, to be opened by the Princess of Wales in April; the Ladies' Residential Chambers, Chénies-street; the Town Hall, Chelsea, won in competition, and the Central Library in Chelsea, also gained in competition, and now building; the Lecture Hall of the Dulwich Presbyterian Church; and joint architect with Mr. Jas. Cubitt of the large Congregational Church at West Kensington. Mr. Brydon gained the first premium in the competition for the Streets Improvement Scheme at Croydon, but which was never carried out; his design for Kensington Vestry Hall we remember as the best submitted, but it was not chosen. He was elected a Fellow of the Institute in 1881. His photograph is by Mr. Bassano, of Bond-street.

Mr. Thomas Graham Jackson, M.A., F.S.A., sometime Fellow and now Honorary Fellow of Wadham College, Oxford, was a pupil of the late Sir George Gilbert Scott, R.A. His principal works comprise the New Examination Schools of the University of Oxford, which were begun in 1876 and completed in 1888, by the addition of the building for the non-collegiate students of the University; the restoration of the Bodleian Library; new quadrangles for Trinity and Brasenose Colleges, the latter with a frontage to "the High"; new buildings for Lincoln, Corpus, and Hertford Colleges, and for the Ladies' College at Somerville Hall. Restoration of the old sacristy and of the exterior of the chapel at Merton College; enlargement of the choir of the chapel at Oriel, with a new organ gallery and organ case; an organ gallery and organ case at Wadham College chapel, and an organ case for the Sheldonian Theatre. The New High School for the City of Oxford, and the High School for Girls at Oxford, which was built for the Girls' Public Day School Company. He also designed Mr. Cruikshank's boarding-house at Harrow School, new schoolhouse and class-rooms for Uppingham School, new boarding-houses and other buildings for Brighton College, and new buildings for Cranbrook School, Radley College, and the Military College at Cowley. Several private residences in London and the country. The new Town Hall at Tipperary; new churches at Wimbledon, Anerley, Stratton, Worthington, Narberth, Homblyton, Curdrige, the memorial church of Bishop Patteson on Norfolk Island, refitting and decoration of the choir of St. John's Church, Hampstead, and the restoration and refitting of the chapel of Blenheim Palace. Extensive alterations and additions to Messrs. Powell's glass works at Whitefriars. Blocks of model dwellings for artisans and labourers at Hampstead, and a street of model cottages, with a coffee-house attached, at Sevenoaks. Mr. Jackson was one of the nine British architects distinguished at the Paris Exhibition of 1878. He was awarded a medal at the Sydney Exhibition, also a medal and diploma of the first order of merit at the Adelaide Exhibition of 1887. He was one of the six architects invited to compete for the Imperial Institute, 1887. He was not an exhibitor at Paris, 1889. Among his literary works are "Modern Gothic Architecture" (H. King and Co.), "Dalmatia, the Quarnero and Istria," in 3 vols. (Clarendon Press, Oxford, 1887), "Ragusa" (in Italian), Zara, 1886, and various pamphlets, lectures, and articles in periodicals on architectural sub-

jects. His portrait is printed from a photograph by Messrs. Russell and Sons, of Wimbledon.

Mr. Basil Champneys, B.A., whose photograph comes next on our sheet, was the architect of Mansfield College, Oxford, recently opened. He built the new buildings for New College, and the Indian Institute at Oxford. At Cambridge he was architect to the Archaeological Museum, the Divinity and Literary Schools; and for Newnham College his works comprise the Old Hall, Sidgwick Hall, and Clough Hall, Cambridge. At Harrow he erected the Butler Museum and classrooms; and at Bedford the Harper Girls' School and new Grammar School buildings. Among Mr. Champneys's new churches are St. Luke's, Kentish Town; St. Peter-le-Bailey, Oxford; St. Mary Star of the Sea, Hastings; Havering-atte-Bower, Essex; Matfield, Kent; Stonefold, Lancashire; and Glas-cote, near Tamworth. He has restored a good number of old churches, and built numerous new houses and vicarages about the country. Mr. Henry Holiday's house at Branch-hill, Hampstead, was an early example of his domestic buildings; and his own house, "Manor Farm," Hampstead, built in 1880, was illustrated also among our series of "Artists' Homes" on July 9th of that year. The Fawcett Memorial, erected by the women of England in the gardens of the Thames Embankment, was designed by Mr. Champneys, who has also made a design for a vast block of residences in flats at Kensington, called "Park Mansions." He is well known as a contributor on architectural subjects to the magazines and reviews, and in this way wrote strongly on the completion schemes for St. Paul's Cathedral. Last year he read a paper before the R.I.B.A. on the proper treatment and more frequent use of ornamental plasterwork for decorative building. The photograph of Mr. Champneys was specially taken by Mr. Thomas Fall, of 9 and 10, Baker-street, Portman-square, W.

Mr. William Henry Crossland, F.R.I.B.A., pupil of Sir George Gilbert Scott, R.A., was the architect of the Royal Holloway College at Egham, and the Holloway Sanatorium, both buildings of the first magnitude. He designed Rochdale town hall, the Post Office, Huddersfield; a clubhouse; the Church Institute and the Ramsden Estate buildings in the same town, besides some blocks of offices, warehouses, and shops there. His new churches are St. Stephen's, Copley, Halifax; Trinity Church, Ossett, Wakefield; St. Mark's, Sheffield; four churches at Huddersfield; another at Flockton; Christ Church, Staincliffe; St. Chad's, Headingley, Leeds; St. John and St. Mary chapels at Ripon. He restored the parish churches of Birstall, Masham, Elland, Almondbury, Womersley, and Kellington. He has built several schools and parsonage houses, and his mansions include Longley Hall for Sir John W. Ramsden and Rishworth Lodge for the late Mr. Henry Savile. He also designed Akroydon at Halifax. His portrait is the work of Messrs. Maull and Fox, of Piccadilly, W.

Mr. John Belcher, F.R.I.B.A., Member of the Institute Council, is the architect of the Institute of Chartered Accountants now erecting in Finsbury. In conjunction with his father, the earlier work of the firm comprises houses on the London Bridge approaches, King William-street, Eastcheap, Indian buildings (now the Cannon-street Terminus), and other premises built in Cannon-street; a church and almshouses at Northfleet; the Royal Insurance Buildings, &c., Lombard-street; the Commercial Union Fire Office, Cornhill; the Public Hall, Croydon; country seats at Epsom, Windsor, Gomshall, &c.; alterations to South Hill Mansion; Shirley House, Croydon; Encombe House, Dorsetshire; schools and house, Kingston; factories at Kentish Town and Ratcliffe; warehouses Botolph-lane and Thames-street; and some paper-mills at Dartford. More recent works include the Carriers' Hall, London-wall; Mansion House-buildings for Messrs. Mappin and Webb; some premises in Newgate-street; No. 1, Poultry; the Catholic Apostolic Church, Camberwell; and premises in Wood-street, Cheapside. Mr. Belcher, jun., has erected Morden Grange; Stowell Park; Holcombe Wood, Chatham, Kent; some houses on Chiswick Mall for Mr. Thornycroft; a house near Blackheath Hall; Norwood District Cottage Hospital; stables, North Leach, Gloucestershire; studios and stables, Weirleigh; and other country buildings. He made a design for some art galleries at Kensington, and a church

at Maida Vale, both shown at the Royal Academy. He restored South Marston Church, Wilts. His design for the tower and spire to the late Raphael Brandon's great Irvingite Church in Gordon-square, exhibited years ago, has not yet been carried out. Last year Mr. Belcher read a paper on "the Development of the Organ for Churches" before the R.I.B.A. His portrait is photographed from a bust exhibited at the Grosvenor Gallery a year or two since, by Mr. Hamo Thornycroft, R.A., and never before published. Mr. Belcher, in sending it, says:—"It may possibly prove of more interest than the subject, being the work of so eminent a sculptor. The portrait is said to be very good indeed."

Mr. John Gordon, I.A., the President of the Glasgow Institute of Architects, has been in practice as an architect for about 28 years, during which time he has built a considerable portion of the warehouse and business properties of Glasgow and neighbourhood, inclusive of mills, stores, factories, &c. He has also a fairly extensive practice in mansions, villas, and other country houses. Among his works are Clevedon, Ravelston, Westmount, and Gordon Lodge, Kelvin-side; Oakleigh and Creggandaroch, Blairmore; Woodlands, Haselbank, and Milverton, Pollok-shields; Crookston and Calton Public Schools, Baltic Works, Grove-park Mills, and Kingston Stores, Glasgow; Regent Mills, Partick; Lace factory, Newmilns; and additions to the Wool Exchange, London. The portrait is by Messrs. Adamson Bros., Glasgow.

## BEHAVIOUR OF IRON COLUMNS SUBJECT TO FIRE.

THE many experiences during fires in large city warehouses have proved that iron columns and girders subjected to fire or heat, and afterwards cooled, have given way and rendered the preservation of the structure hopeless. Generally it has been assumed that cast iron is the most untrustworthy metal in this respect; but experiments have proved that cast-iron columns withstand the action of fire and water better than wrought-iron columns. Both were loaded and heated, and then suddenly cooled by jets of water, and it was found that the cast-iron columns continued to support the load even when red hot and cracked, whereas wrought-iron columns collapsed when similarly treated. These experiments were conducted in Munich. There were some grounds for thinking that cast iron was more liable to crack and fly to pieces than wrought iron; but if these results are as reported, there is more danger in the employment of wrought iron. In Berlin, the building regulations in force insist that cast-iron columns, not protected from the action of fire, may not be placed under the main walls of buildings, but instead of them wrought iron may be used, a rule showing how firmly the above assumption is held.

The reredos of Lillington Church, near Leamington, has now been completed by the addition of side wings of Caen stone, with marble columns and mosaic panels, designed to harmonise with the central portion, or reredos proper. A description of this—which consists of a large panel of Caen stone, embellished with a representation of "The Last Supper," carved in high relief, and enriched with columns of Devonshire and Derbyshire marbles—has already appeared in this paper. The effect of the whole structure is extremely rich. These additions were intrusted for execution to Messrs. Jones and Willis, of Birmingham and London.

Major Marindin, on behalf of the Board of Trade, made the official inspection of the new Stockbridge Cable tramway at Edinburgh on Friday. Mr. W. N. Colam, the engineer of the Edinburgh Northern Cable Tramway Company, was in attendance, and the Corporation of Edinburgh, as the Local Authority, was represented by Bailie Steel, the Borough Engineer, Mr. Cooper, and the City Road Surveyor, Mr. Proudfoot, being also present. The portion of the line inspected was that extending from the depot in Henderson-row to Stockbridge, the remainder of the route having been officially examined and passed a considerable time ago.

The annual meeting and distribution of prizes in connection with the Devizes School of Science and Art took place on Friday evening. The report of the committee referred to the continued success of the school under the management of Mr. William C. Coles, the head master. The total number of students was 97, a decrease of five on the previous year. An address on art was afterwards given by Professor J. E. Hodgson, R.A.

## Building Intelligence.

**BROMLEY, KENT.**—On Tuesday last the new baths, grand hall, and theatre were partly opened. The entire scheme is unique, the building being cut into a hill in the rear of the High-street, and 35ft. below the level of the High-street, so that although the baths are under the theatre, the floor of the theatre is about level with the pavement in the High-street. The building is executed entirely of concrete, even to the floor of the theatre. The total site of the building is 110ft. by 55ft. wide; the size of the bath is 80ft. by 35ft., and is lined with white-glazed bricks. The floor over the bath is of compound-iron girders, 250lb. to the foot, resting on 9in. C.I. columns; the whole of the ceiling over bath is rendered in Robinson's cement upon wirework, thereby rendering it absolutely fire-proof. There is box accommodation for forty bathers; while the lavatory accommodation here, as in other parts of the building, has been thoroughly considered. The method of emptying the bath into the sewer is by a receiver 30ft. deep below the bath, from whence it is pumped into the sewer. The machinery is being fitted for heating the bath to 70 or 75deg., pumping all the water supply from a well, which has been sunk upon the site to a depth of 300ft., emptying the receiver into the sewer, in addition to heating the hall, and is a thoroughly-developed plan by Messrs. Russell, of Oxford-street, W. The spacious hall and theatre, 80ft. by 35ft., is built lofty, and has a domed ceiling, the lighting being on the most improved system, with two immense sun burners, well ventilated. The main entrance from the High-street is by a wide corridor and crush-room, 35ft. by 22ft., with efficient doorways to hall, with additional exit doors on each side, for which a verandah of iron has been erected at one side leading to the road and fields in rear of premises, all the doors being fitted with panic fittings. A large and lofty stage, with excellent arrangement for working the scenery, the stage front having a fire-resisting curtain, while a large orchestra is provided at the other end to meet the requirements for orchestral entertainments, serving as a gallery during the theatrical performances. Mr. W. A. Williams, A.R.I.B.A., is the architect, the works having been well executed by Messrs. Thos. Gregory and Co., of Clapham Junction, S.W.

**COVENTRY.**—A meeting of the general committee for the restoration of the spire and church of St. Michael's, Coventry, was held on Friday. Lord Leigh presided. Mr. J. Oldrid Scott, the architect for the restoration, stated that the stone groining in the tower was completed, and would be a very beautiful feature in the tower. The whole of the restoration proper was finished, but the carved figures had to be placed in their niches. Mr. Seymour (hon. secretary) gave a financial statement, showing a sum wanted of £5,839. Mr. Scott said there was no true provision for ringing in the tower, but it was possible to re-hang the bells at a height of 110ft. and chime them. Mr. Caldicott moved that the bells be rehung in the tower and chimed. Mr. Mander seconded. Mr. G. Woodcock argued that the people of Coventry and the county would not be satisfied with chiming merely; they would want them rung. This would necessitate a new bell-tower, which would cost £10,000 in round figures. He proposed that the bells be not rehung until the feeling of the whole of the inhabitants was ascertained by testing their willingness to subscribe £5,000 towards a new bell-tower. Lord Leigh strongly deprecated the erection of a new and separate bell-tower, and said many subscribers shared that view. After a protracted discussion, it was decided that the matter be allowed to rest till after the next election of churchwardens, who, with the vicar, were the legal custodians of the bells.

**LONDON COUNTY COUNCIL.**—At the meeting of this body on Tuesday the chairman intimated that he had received a letter from Mr. Clement Dunscombe, late of Liverpool, who was only recently appointed the chief engineer to the Council, in succession to the late Mr. Joseph Gordon, resigning his post in consequence of ill-health. After some discussion, it was agreed to refer the matter to the standing committee, in consultation with the chairmen of the main drainage, highways, improvements, and bridges committees, to recommend to the Council a suc-

cessor to Mr. Dunscombe. The post has attached to it a salary of £1,500 a year. We understand that the joint committee will recommend to the Council the appointment of Mr. A. R. Binnie, water engineer to the Bradford corporation. The main drainage committee reported that, in accordance with a resolution instructing them to secure the "services of an eminent civil engineer to join the engineer of the Council in a thorough examination of the whole sewerage system; that the engineers be desired to include in their report an approximate estimate of the cost of taking the whole of the sewage to sea," they had obtained from Mr. Benjamin Baker his consent to act with the engineer of the Council, his fee to be a retaining fee of 50 guineas, and 15 guineas per day occupied, the whole not to exceed 500 guineas. The arrangement was formally approved. The election took place of an assistant engineer in the place of Mr. Lovick, at a salary of £600 a year. Sixty-seven applications had been received, subsequently reduced by a committee to forty-four, and ultimately to three, Mr. W. Santo Crimp, of Wimbledon, Mr. A. B. Allan, burgh surveyor of Govan, N.B., and Mr. H. A. Roeckling. A division being taken, Mr. Crimp received 47 and Mr. Allan 46 votes, the former engineer being elected by a bare majority.

**NEWPORT, MON.**—The foundation-stone of new model lodgings was laid on Wednesday week by the Mayor on a triangular site abutting on New Dock-street and Corn-street. The edifice—a plain one—will rise to three stories, and will be Italian in style. Ornamentation will be secured by projecting windows of buff brick, a curb roof, with dormer windows breaking the sky-line, and ventilating on the roof. The fronts will be in Risca blue Pennant rock work, relieved with Ebbw Vale brick and Bath stone. In the basement there are to be two large cellars. The ground floor will consist of a dining-kitchen, 40ft. by 20ft., with a scullery 20ft. by 12ft., together with entrance-halls from Dock-street and Corn-street; a main hall, open fireproof stairs continuing to the top of the building, ticket-office, and rooms for the manager. At the back will be a large yard for light and ventilation. On the same floor there will be a shop, with plate-glass front, to Dock-street, 30ft. by 18ft. On the three upper floors will be dormitories, divided off for men and women. On the first floor the bedrooms will be 11ft. high from floor to ceiling, but on the others 10ft. The premises may be registered for 200 inmates. The contract for building has been let to Mr. John Linton at £2,460, but, with furnishing and fittings, the total cost will be brought up to over £3,000. The work is being carried out from designs of Mr. E. A. Lansdowne, architect, Newport.

**PETERBOROUGH.**—The restoration of the choir, lantern tower, and transepts of Peterborough Cathedral having been completed by Mr. John Thompson, builder, of Peterborough, from the plans of Mr. J. L. Pearson, R.A., the Dean and Chapter are now in want of funds to furnish the choir. Several stalls have been promised and a fund has been opened to present two stalls on behalf of the Freemasons of England as a memorial of the Masonic ceremony which took place on the occasion of the laying of the foundation-stone of the central tower by Lord Carnarvon in May, 1884. The Restoration Committee have decided to issue another appeal for funds to proceed with the work.

**PRESTEIGN.**—The restoration of the fine old parish church of Presteign, Radnor, commenced last spring, is making good progress. Mr. J. L. Pearson, R.A., is the architect, and Mr. T. Collins, of Tewkesbury, is carrying out the contract (taken at £2,896) for the first section of the work, including the restoration of roof, fabric, and floors of aisle and nave, and his tender has just been accepted, at £424 10s. for repairs to the tower and the construction of a chamber for warming apparatus. The Saxon windows and arches which have been discovered in the north wall of the church during the restoration are being scrupulously preserved by Mr. Pearson. Remains of the south wall of the old Saxon church have also been found in removing soil from the nave of the present church. Also the removal of the plaster has revealed some frescoes over the north arcade of the nave. It is hoped that these will be found to be sufficiently perfect to be restored. Apparently the figures represent "Life

and Death." The entire cost of restoration, including carved oak stalls, seats, &c., Mr. Pearson estimates at nearly £8,000.

**TAUNTON.**—On the site of the old vicarage of St. James's the Taunton Electric Lighting Company have erected premises as a central station. Through the enterprise of Mr. H. G. Massingham the electric light was introduced into Taunton as an experiment nearly four years ago, the Parade and a few of the principal business establishments being lighted by the Thomson-Houston system. The town council eventually accepted a tender for the lighting of the chief streets of the town. A large stack 120ft. high, 10ft. 6in. at the base, and 5ft. 6in. at the top, denotes the locality of the works. The boiler-house, which is 100ft. by 40ft., is fitted with two of Babcock and Wilcox's water-tube boilers, each of 150H.P. The engine and dynamo-room is 100ft. by 50ft. The wires outside will not only be insulated on fluid insulators, but will have a quarter of an inch covering of pure indiarubber, and the wires are to be placed at a height of 30ft. Mr. H. J. Spiller has carried out the building contract, the architect being Mr. F. W. Roberts.

**TORQUAY.**—The second section of the new Church of All Saints, Torre, was opened on Friday last. The church has been built from designs by Mr. J. L. Pearson, R.A., at a total cost of £11,000, and the first, the eastern portion, was opened in 1886. All Saints is cruciform on plan, having a nave 88ft. long by 24ft. wide, with north and south aisles each 12ft. wide, transepts measuring 65ft. from north to south, and secondary transepts of similar dimensions at the west end of the nave. The chancel forms an apse 36ft. deep, with polygonal termination of the same width as the nave. The architecture is the fully developed Decorated style of the middle of the 14th century. Local red sandstone has been used in the building, which is faced externally with local limestone, the dressings both inside and out being of Bath stone. The chancel is lighted by a corona of seven windows of two lights each. A specially constructed organ has been built by Messrs. Vowles, of Bristol, on the north side of the chancel, and a special case in harmony with the interior of the church has been designed by the architect. The general contract has been carried out by Mr. F. Matthews, of Babbacombe, Mr. E. T. Price being the clerk of works. Some of the carving, including the bishop's chair with the arms of the diocese, is by Mr. Harry Hems, of Exeter.

**THE HOUSE OF COMMONS.**—During the recess a number of alterations have been made in the House of Commons, with a view to providing Ministers and members generally with additional accommodation. Some officials have been removed to the buildings adjoining Westminster Hall, and their rooms—five in number—will be placed at the disposal of members. A new smoking-room and an additional reading-room have been provided on the terrace; and in Palace-yard an ornamental shelter has been provided for the horses of members, in lieu of the shed which formerly flanked the entrance to Westminster Hall. A new ladies' dining-room has also been provided. The grand committee-room, erected on the site of the old Law Courts, is now practically ready for use. The space in front of this structure is to be laid out. In the mean time a low wall is to replace the existing 10ft. wooden hoarding.

**WESTMINSTER: THE CHURCH HOUSE.**—At a meeting of incorporated members and supporters of the Church House, London, held at Norwich on Saturday, the permanent secretary (Mr. Percy Crosse) explained the plans in detail. The Church House buildings, he said, would occupy an acre of ground, which had been purchased for £28,000, besides which £2,000 had to be paid for adapting two houses to the purpose for which they were required. Other houses were paying them rent to the amount of £960 a year, and other leases would fall in shortly. Sir A. W. Blomfield had been selected by the council as architect, and the plans were submitted to the council last Thursday. The elevation had not been drawn yet, and it was thought desirable not to publish the plans till this was forthcoming. The entrance to the Church House would be from Dean's-yard, and a little to the right would be the entrance arch, which would lead into a small square. In the centre would be a quadrangle; on the right would be the entrance-hall, with a large staircase leading to the first floor, where

the principal rooms would be placed. On the ground floor would be the secretaries' offices, refreshment-room, and committee rooms. On the first floor would be provided rooms for the Houses of Convocation, divided by partitions, which might be thrown into one; there would also be a room for the House of Laymen. Arrangements had been made for the erection of a small chapel on pillars if it were found necessary, but this would not interfere with the corridor or cloisters on the ground floor. The approaches to the large rooms would be by four different entrances, so that ingress and egress would be easy, and the great hall when thrown open would accommodate 2,000 persons. A library would also be provided beneath the large hall, but at present the houses in which 8,000 valuable books had already been placed would be utilised for the purpose. The third floor would be approached by a lift, and would be devoted to offices for Church societies. Altogether £70,000 had been received, and this had been expended with the exception of about £16,000. The annual income, however, reached an average of £3,000 or £4,000.

### ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

**MANCHESTER ARCHITECTURAL ASSOCIATION.**—The last meeting of this association was held at the Diocesan Buildings on Tuesday. Mr. J. H. Woodhouse, President, in the chair. Mr. J. A. Gotch, F.R.I.B.A., of Kettering, read a paper on "The Homes of Queen Elizabeth's Courtiers." After giving a general sketch of the domestic arrangements of the homes of the nobles prior to this period, he pointed out that it was about this epoch that house planning took a new departure; here, as formerly, safety from invasion was the chief object to be attained even at the sacrifice of convenience. Internal comfort began to be studied, light was admitted by large window openings in place of narrow slits. In speaking of Hardwick Hall, with its large and numerous windows, Lord Bacon remarked, "there was too much light, it was impossible to get out of the sun always streaming through the windows." The paper was illustrated by views shown by an oxy-hydrogen lantern. A vote of thanks was proposed by Mr. Booth, seconded by Mr. Davies Colley, and supported by Messrs. Mould, Mee, Hodgson, and Chadwick.

**DUNDEE INSTITUTE OF ARCHITECTURE.**—Under the auspices of this institute on Friday a lecture on "The Historical Aspect of English Architecture During the Middle Ages" was delivered at the Y.M.C.A. hall by Mr. Mark Hunter, B.A., Oxon. Mr. T. Robertson presided. Mr. Hunter said the study of architecture occupied a place in general history altogether out of proportion to its real importance. One of the chief differences between the mediæval and modern man was that the first invariably found in his simple surroundings conscious strivings after beauty, whilst the latter carelessly contemplated a host of makeshifts. The architect more than any other artist was bound by the law of supply and demand. He had to give the public what the public demanded, and the public was scarcely competent to demand the best. The conditions of modern life were hostile to the development of a noble school of architecture. The necessity of such a society as the Society for the Protection of Ancient Buildings should make them blush for their boasted enlightenment. It would be advisable if the architectural and artistic aspect of history found a place in their schools alongside that record of futile and obsolete legislation which was generally served up to the young under the name of history.

A new Post-office was opened on Monday in Saville-street, opposite the new Market, North Shields. The premises meet a want long felt in the borough of Tynemouth. On the ground floor are the public office, sorting office, postmen's kitchen, store-rooms lavatories, and battery-rooms. On the first floor are the instrument-room, telephone-room and lavatory. On the second floor are the caretaker's apartments and lady clerks' retiring-rooms. Behind the premises is accommodation for vehicles. The contractors for the building have been Messrs. Tyrie and Graham, Gateshead, the fittings being supplied by Mr. Joseph Elliott, contractor, North Shields. The architect is Mr. Henry Tanner, of H.M. Office of Works, London, and the clerk of works is Mr. Searchfield, of the same department.

## Engineering Notes.

**PRESTON.**—At the last monthly meeting of the town council, a formal resolution for the promotion of the new Ribble Bill was carried without opposition. An agreement between the corporation and the executors of the late Mr. T. A. Walker, contractors for the Ribble Works, for resuming and completing the river and dock works at an addition for interruption of 20 per cent. (£19,000) on the work still to be completed was adopted. In explaining the reasons for making this agreement, Ald. Forsham said he went to London to offer 5 per cent., but owing to the advance of material he increased the offer to 10. He was told Sir Edward Watkin had advised the executors not to accept less than 30 per cent., and he found they would either have 20 per cent. or go to two arbitrations. Mr. A. F. Fowler, of York, was unanimously appointed resident engineer for the Ribble Works, in accordance with the interim report of the Ribble Navigation Commission.

**SOUTHAMPTON.**—The Harbour Board have determined to construct a new pier, which is estimated to cost about £20,000. The present pier has become totally inadequate for the traffic, especially upon concert nights in the summer season. The plans include a new railway station, with covered platforms and a new orchestra. The actual area to be covered by the new structure is 2½ acres. There will be 7½ miles of girders used, about three miles of iron piles, 1½ mile of wooden fender piles, 12½ miles of bracings to the piles, and the wood joists placed end to end will be equal to a distance of 21 miles. There will be 90,000 drillings for the bolts and rivets in the wrought ironwork alone, and about 17,000 rivets, 37,000 bolts, nuts, and washers, and 3,000 screw bolts. For a length of 250ft. southward from the quay wall and east of the present entrance, a concrete wall will be constructed joining with the railway embankment, the back of which will be filled in, so as to make the pier for that distance a solid structure. The widening of the pier will allow of a promenade 20ft. in width. On the east side of the new entrance will be a main carriage entrance, and to the eastward an inclosure will be set apart for the penning of cattle. Six landing stages will be provided for steamers on the new pier. Four alcoves will be constructed at intervals along the pier, with cast-iron standards and back, glazed with clear plate-glass, and about 8ft. in height. The west side of the widening will be fenced in by cast-iron railings, with a handrail. An entirely new railway station will be erected, with covered platforms and long open platforms for the convenience of passengers. Around the band stand will be fixed some sheltered seats in polygonal form of twelve equal sides. The house proposed to be rented by the Royal Southampton Yacht Club will be erected on the top of the pontoon bridge, and will consist of club room, lavatories, and covered verandahs. The plans have been prepared by Mr. Poole, surveyor to the Harbour Board, and the quantities, which have been issued to contractors this week, were prepared by Messrs. J. H. Blizard, of Southampton, and H. J. Weston, surveyor to the Freemantle local board.

The memorial statue of Mr. Bright, which is to be erected in the Town Hall-square, Rochdale, and which is to be the work of Mr. Hamo Thornycroft, R.A., will be of bronze, 9ft. in height, placed on a moulded grey granite pedestal, 11ft. high. The sketch model for the statue has been accepted by the committee, and it represents the right hon. gentleman speaking before an audience, with the right arm raised, while the left is lower, and holds the notes for the speech; and the orator is wearing a frock coat, which is blown back as if facing the breeze.

A new model lodging-house in Grassmarket, Edinburgh, was formally opened on Wednesday week. It is of four floors, the ground story being occupied by a dining-hall 55ft. by 47ft. and 20ft. in height, and also by reading-rooms and kitchen. The three floors above are dormitories partitioned off into 384 cubicles. Mr. Jardine, of Edinburgh, was the architect.

On Saturday the students of engineering in the University of Edinburgh, accompanied by Professor Armstrong and Dr. A. C. Elliot, visited the Leith Docks. The party was conducted by Mr. Peter White, M.Inst.C.E., engineer to the Leith Docks Commissioners.

### SCHOOLS OF ART.

**ROYAL FEMALE SCHOOL OF ART.**—The annual distribution of prizes to the students of this school took place at Goldsmiths' Hall on Wednesday week. The hon. secretary to the school, Mr. Francis Bennock, read the thirtieth annual report of the committee, stating that during the past year 159 students received art instruction. Works to the number of 687 were sent in for examination and competition to South Kensington. In the competitions the students of this school in many instances achieved success. Only five sets of hands drawn from the life were selected from among all the works sent in for exhibition at the national competition, South Kensington, and of these four were from the Female School of Art. Two of these drawings were purchased by the Department. Excellent reports have been received of the success in various parts of the world of former pupils. The chromo-lithographic studio, at which pupils are taught and afterwards employed, has continued to show progress. New buildings have recently been added to the school; but there still remain debts to be liquidated. The committee therefore appeal for contributions to complete the sum of £2,000 which is required. The Queen's scholarship has been awarded to Edith M. Flack, and the Queen's gold medal to Edith Harwood for a drawing from the antique of the Venus of Milo. Mr. Roscoe Mullins delivered a short address to the students.

**SALISBURY.**—The annual distribution of prizes to the successful students of the Salisbury School of Science and Art took place on Thursday evening, the 30th January, at the Art Gallery. The Mayor, Mr. Geo. Nodder, occupied the chair. The annual report stated that the number of students had been 120, an increase of six on the previous year, and the grant showed an increase of £7 in science and £12 in art. A large amount of interest was awakened by the fact that the meeting was being held in the new Art Gallery, which has been built at the cost of Dr. Roberts on the site of the old theatre, from plans by Mr. M. Harding, carried out by Mr. Hale.

### CHIPS.

As the Surrey County Council will be unable, after two years, to use the Sessions House at Newington-causeway, it was resolved, at a special meeting of that body on Tuesday, to take steps for providing accommodation for the transaction of the future business of that body, including a Council Chamber, Committee Rooms, County Offices, Record Rooms, and a Quarter Sessions Court, and a committee was appointed to select a site for the new buildings within the county's administrative area.

Two donors have contributed a thousand pounds each towards the proposed fund of £15,000 now being raised by the Bishop of Peterborough for erecting churches at Leicester. Three churches are to be commenced immediately, and sites for two of them have been given.

The North-Eastern Railway Company are seeking Parliamentary powers this session for extensive works of reconstruction in Newcastle. The alterations include the extension of the Central Station, by which, with the works now in progress the area of the station will be increased by one half. A new loop line to be constructed entirely on lofty arches, will be carried from the foot of the High Level bridge to the east of the Central Station, passing between the Old Castle and the Moot-hall, while the existing lines through the city both east and west are to be doubled in width.

The Croydon town council have unanimously confirmed a resolution passed at a previous meeting, to promote a Bill in the present session of Parliament to acquire property to widen High-street and abolish Middle-row, at an essential cost of £146,000. Negotiations have taken place between the Council and the Brighton Railway Company, which have resulted in an agreement for the purchase by the Corporation of the Central Railway Station site for £12,000, for the purposes of a new town hall.

A portion of the Cloth Hall site in Leeds, containing 5,525 square yards, has just been purchased of the corporation of that borough by H.M. Office of Works for £44,200, for the purpose of erecting thereon a new and larger and more convenient Post-office than the existing one in Park-row.

At a vestry meeting held at the parish church, Weston-super-Mare, on Friday, plans for the addition of a south aisle, prepared by Messrs. Hans Price and Wooller, of that town, were approved. The aisle will complete the church, and will accommodate 200 persons at an estimated cost of £1,350.

## TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

## TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 80c.) To India (via Brindisi), £1 10s. 4d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

## ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

## SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING for TWENTY-FOUR WORDS, and SIXPENCE for every eight words after. All Situation Advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page advertisements and alterations in serial advertisements must reach the office by Tuesday Morning to secure insertion.

## NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XLI, XLVI., XLIX., L., LI., LIII., LVI., and LVII. may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—W. and R. C. L.—S. S. B.—B. and C. L. B. J. C. G.—E. K.—B. and Co.—C. N. and Co.—J. C. E.—J. B.

## "BUILDING NEWS" DESIGNING CLUB.

FAIRPLAY. (We fully considered your point before making the award.)—P. BROCKBANK. (No w.c. or lavatory are to be provided, or such would have been stated. Follow the instructions.)—COSMOS. (If you will send your drawings unstamped we cannot take them in.)

## Correspondence.

## THE MOSQUE OF TOULOUN.

To the Editor of the BUILDING NEWS.

SIR,—In my first Royal Academy lecture, published in your issue of the 31st ult., I said, "The Koptic architect who built the brick mosque for Touloun in the 9th century . . . possibly was the introducer of the small arches that take the place of pendentives in the dome." My friend, Mr. R. Phené Spiers, has pointed out that these arches are not coeval with the original mosque.

Mr. Stanley Lane-Poole, in his "Art of the Saracens in Egypt," says of the brick dome, at p. 54, "It was built, however, a century later than the mosque itself"; and at p. 64, "There is such a cupola over the niche in Ibn-Tulun, though this is probably of the date of the restoration by Lagin in 1296, to judge by the wooden stalactites which are found in no other part of this mosque."—I am, &c.,

G. AITCHISON.

150, Harley-street, W., Feb. 4.

## BRUGES.

SIR,—I noticed, during a visit to this place last week, that a large number of the ordinary old house-fronts were being restored, and was informed that an impetus had been given to this work by the offer of the municipality to pay one-third of the cost of the façades, provided the work be properly done. My authority for this

statement is M. l'Abbé Isaak, of the Augustinian Convent.

Some restoration is proceeding behind a hoard in the upper part of the tower of Notre Dame, and I understand further restorations are unfortunately contemplated to the beautiful group of buildings at the east end of it, lately used for the Mont de Piété.

A very large block of buildings has been erected in the neighbourhood of the Basin for a normal school, and this, with the railway-station and the State buildings of the Grand Place, are all designed in the local 15th-century style. Altogether there has been considerable briskness in building operations in the old Flemish city during the last twelve months.—I am, &c.,

J. TAVENOR PERRY.

## BARTON TURF AND FRITTON SCREENS, NORFOLK.

SIR,—The admirable reproductions which you gave lately from the folio printed by the Norfolk and Norwich Archaeological Society of the Randworth screen were most beautiful and interesting. I had often endeavoured to obtain a copy without success. Could you not give some of the plates issued by the same enterprising society years ago of Barton Turf and Fritton screens? Although not so rich as the Randworth example, they are both well worthy of illustration in your pages.—I am, &c. A DECORATIVE PAINTER.

[We should be happy to carry out this suggestion if some one would lend us a copy of the two folios of plates referred to by our correspondent, and we have already obtained the permission of the Norwich and Norfolk Archaeological Society to republish them.—ED.]

## CHIPS.

The West Cornwall Hospital for Women, which has recently been erected on a site adjoining the Miners' Hospital at the West End, Redruth, was formally opened on Wednesday week by Mrs. Basset, of Tehidy. The outlay on building and furnishing has been £1,500.

According to *Truth*, the Americans' love of gigantic tombstones and monuments is highly profitable to the Aberdeen granite merchants, who send £60,000 worth of stone every year to the United States, nearly the whole of which finds its way to the cemeteries in which wealthy Americans are buried.

The Crown are at present engaged in planting Greeba Mountain in the Isle of Man, and Messrs. Wm. Fell and Co., nurserymen, of Hexham, have received an order from her Majesty's Commissioners of Woods and Forests to plant 110,000 transplanted Scotch firs, as well as a large quantity of other hard woods to plant along with them.

On Saturday a new water supply for the village of Stanley, seven miles north of Perth, was turned on by the Duke of Athole, K.T., Lord Lieutenant of the county. A drainage district was formed some time ago, and it was resolved to tap the springs of the Shochie, a stream which takes its rise at Shenval, near Glenshee, on the Duke of Athole's estate. Plans were prepared by Mr. James Ritchie, C.E., Perth, and the work has been carried out at a cost of nearly £3,000.

The village of Pinxton, Derbyshire, is about to be seweraged at a cost of £2,550. Mr. H. Walker, of Nottingham, is the engineer, and Mr. J. F. Price the contractor.

A new club has been erected at Swindon, and special attention has been paid to the ventilation, which is carried out on the Boyle system, the extraction of the vitiated air being effected by the latest improved form of the self-acting air-pump ventilator, and fresh air admitted by improved air inlets.

A reredos erected in the Scandinavian church at Grimsby has just been unveiled. It is in the Early English style, and in the centre a large space is occupied by a fine old oil painting by F. Boye, executed in 1815: subject, the "Crowning of Christ with Thorns." Above is a stained-glass window with a representation of the "Resurrection of Christ."

The work of rebuilding the Taliskers Distillery in the Isle of Skye is being pushed on rapidly from the designs and under the direction of Mr. Charles C. Doig, architect, of Elgin. A recent fire destroyed so much of the old buildings as to render the erection of new necessary. The latest improvements and appliances are being introduced.

Plans are being prepared for additions to the mansion, Thirkleby Park, Thirsk, by Messrs. Wm. Lewis and Son, architects and surveyors, Stonegate, York, for Lady Payne Frankland.

## Intercommunication.

## QUESTIONS.

[10220].—**French Chateaux.**—Could any of your numerous readers give me a list of about a dozen of the most typical French Chateaux, with, if possible, date of erection and name of architect?—M.

[10221].—**Staining Marble.**—I have a handsome white marble (grey veined) mantelpiece which I want to stain a full yellow tone, as the effect is too cold. Will anyone kindly tell me how to make the stain, or what to use? I have asked a marble-mason, and he can't tell me; yet nothing is more common than to see yellow stains on marble which the owners are unable to get rid of.—SIGMA.

[10222].—**Billiard-Room Floor.**—Would some kind and capable reader oblige by letting me know if 12in. by 3in. red Swedish or pitch-pine joists, fixed 12in. apart, are strong enough for a billiard-room floor of 25ft. 6in. clear span; one room is to be 43ft. long on the first floor, and to carry three tables. Under each set of table legs we propose fixing two joists bolted together, and to further stiffen floor by putting in three courses of bridging, in the centre course with 3in. or 3in. iron bolt running the 43ft., with 12 by 1½ bridging, and in the two spaces between centre bridging and walls to fix cross-bridging, with two courses of hoop-iron to each, going over top of one joist to under of next, and so continued throughout, so forming diagonal ties from joist to joist, and tightening the two courses of cross-bridging. Would floor thus formed be sufficiently strong for the usual load on room of this size and class? Prompt answer would indeed oblige.—K.

[10223].—**Trade Union Rate of Wages.**—Will some reader kindly tell me the union rates of wages in the building trade in London, or where I can obtain this information.—M.

## REPLIES.

[10215].—**Wood-Block Floor.**—It is now not far from 40 years ago that I first invented the flat wood-block paving. I may, therefore, be entitled to reply to "Saw-set." It was, however, some years later, after unpleasant experiences, that I discovered the necessity of laying them absolutely free from moisture in any form; and again, subsequently I learnt the need of greater care than is commonly used to have any concrete or cement beneath not only thoroughly set, but properly dried out before laying them. The wood is certain to absorb the moisture as it dries out, and if any earthy or vegetable matter be present, it will induce decay. The blocks swell with moisture, and on drying again, wide cracks are formed, which loosen them, and let in more wet. Moreover, if the concrete be wet beneath, it will inevitably throw up through the joints any tarry substance in which the blocks may be set, and make them dirty and black. I have found "Boreham's coarse black varnish" a good material for laying them; and, when laid, a dressing of Carbolinum Avenarius, put on hot. This, however, sometimes takes nearly a week to set properly. In setting it is greasy, not tacky; and till properly set it persistently resists varnish, or other finishing coat.—WILLIAM WHITE, F.S.A.

[10215].—**Wood-Block Floor.**—The wood blocks ought to have been laid in a composition specially prepared; the wood blocks that are rotten were no doubt cut from unseasoned wood. The composition is a bituminous mixture; but common pitch and tar would have prevented the rottenness. Take up decayed blocks, and relay on Lowe's system.—G. H. G.

[10215].—**Wood-Block Floor.**—I have several mes pointed out in your correspondence columns that it is a great mistake to bed well-seasoned blocks in cement mortar, for they are certain to come loose, and sooner or later have "dry-rot" in them. The heat from the hot-water pipes sets up more quickly the action of "dry rot," and these blocks will be the worst sufferers. To remedy the defects, and to make sure "dry rot" will not return, the whole of the present blocks will have to be removed and the top floating of cement hacked off, so that a fresh floating of cement-mortar may be put down. When this has become hard, fresh blocks should be laid. Several systems of laying are before the public; but if your correspondent will communicate with me, I will assist him out of his difficulty.—ROGER L. LOWE, Wood-Block Works, Farnworth, near Bolton.

[10217].—**Architect, Client, Builder.**—1. If the architect gives a certificate, the client cannot refuse to honour it. 2. A client, on the receipt of a final certificate, cannot reduce the amount. If it is reduced with the sanction of the architect, the builder has a fair ground to bring an action for collusion if he can prove the facts.—G. H. G.

[10218].—**R.I.B.A. Exam.**—The stipulation for probationary works to be of a definite size is of quite recent introduction, and is somewhat absurd in the face of the announcement that drawings need not be specially prepared for the purpose. If drawings of any size are submitted, with a letter giving a reasonable explanation of the reason for this rule not being complied with, they will be accepted; or, at least, they have been at recent Exams.—G. A. T. MIDDLETON.

[10218].—**R.I.B.A. Exam.**—Judging from what candidates assert as to procedure at recent examinations, I do not think the examiners will reject drawings a few inches smaller than the size required if they are carefully prepared.—G. H. G.

[10219].—**Damp.**—I suspect the dampness of the wall referred to arises from the sand having been impregnated with salt—perhaps sea-sand. The only cure is to strip off the plastering and to use cement; or it would be more satisfactory to battan the wall inside.—G. H. G.

[10219].—**Damp Walls.**—Has "Philo" tried Carbolinum? I have found it very efficacious in expelling damp. But if there be much moisture in the walls, it may take a month or two to effect this. And, till then, it will not itself dry.—WILLIAM WHITE, F.S.A.

## LEGAL INTELLIGENCE.

**IN RE THE EAST AND WEST INDIA DOCK COMPANY.**—In the Chancery Division, on the 29th ult., Mr. Justice Chitty delivered judgment in the petition presented by the East and West India Dock Company, under the Railway Companies Act, 1867, seeking for the confirmation of a proposed scheme of arrangement. The petition was opposed by Messrs. Lucas and Aird, judgment creditors for some £60,000, and Messrs. Kirk and Randall, claiming £650,000. His Lordship said that he was satisfied that the scheme had been duly assented to according to the provisions of the Act by the debenture holders and ordinary shareholders, the former representing more than £3,000,000, and the latter £2,385,500. The scheme had been prepared in good faith by the company, and was not unfair to the outside creditors. The position of the outside creditors was certainly very unfortunate, and their prospects of payment apart from the scheme were not hopeful. He was satisfied that no sufficient objection to the scheme had been established, and he accordingly confirmed it.

**ERECTION OF BUILDINGS CONTRARY TO BY-LAWS.**—(Hopkins and Allen v. the Smethwick Local Board.)—In the Queen's Bench Division on Friday—before Mr. Justice Denman and Mr. Justice Wills, sitting as a Divisional Court—the case of Hopkins and Another v. the Smethwick Local Board came before the Court on appeal from a decision of Baron Pollock, who tried the case with a special jury at the last Staffordshire Assizes. The plaintiff Hopkins is a builder, the other plaintiff—Mr. Allen—is the leaseholder of a plot of ground at Smethwick upon which Hopkins proposed to erect a number of dwelling-houses and shops. The plans were sent in to the Local Board surveyor in due course, but were objected to, on the ground chiefly of the insufficient sanitary arrangements, there being only four privies to eleven houses, the drainage being defective, &c. The plaintiffs, without waiting for the plans to be approved, proceeded to erect the houses. After some progress had been made with them, the defendants' surveyor gave them notice to pull them down. This they neglected to do, and the surveyor sent a body of men, who pulled down the hoarding which inclosed the buildings, and also demolished five houses and one shop. The plaintiffs then sued the defendants for trespass. Baron Pollock held that the defendants had complied with the provisions of the Public Health Act, and directed the jury to find for the defendants, which they did, and his lordship gave judgment accordingly. The plaintiffs now appealed, and asked that judgment be entered for them on the ground that Baron Pollock had misdirected the jury. The following cases were cited for the plaintiffs:—"Cooper v. Wandsworth Local Board" (14 C. B. N. S. 180); "Masters v. Pontypool" (9 Ch. Div. 677, 47 L. J. Ch. 799); "Robinson v. Barton Eccles Local Board" (8 App. Cases, 798). For the defendants "Baker v. Mayor of Portsmouth" (47 L. J. C. P. 223) was relied on. Their lordships came to the conclusion that the defendants were wrong; it was not enough to give the plaintiffs notice to pull down the houses, but they should have given them notice calling upon them to show cause why the houses should not be pulled down, and, further, they should have fixed a date for a meeting of the Board, at which the plaintiffs should have been notified to attend and show cause. That not having been done, the defendants were not entitled to pull down the houses. The judgment of Baron Pollock must, therefore, be set aside, and judgment entered for the plaintiffs, damages £60, the amount agreed upon in case the judgment should be reversed. On the application of Mr. Young, execution was stayed for a week, in view of an appeal.—The effect of this decision of the Court of Queen's Bench is, that before a local board can destroy houses which are being built contrary to the by-laws, they must not only give notice to the builder to pull them down, but further appoint a date on which the builder may attend before the Board to show cause why they should not be pulled down.

**THE SERIOUS CHARGES AGAINST A SURVEYOR.**—At Westminster Police-court on Saturday, John Hill, 41, a surveyor, of Broadstairs, formerly an architect and surveyor at Brighton, was again brought up in custody to further answer charges of embezzlement and forgery. The prisoner, from March, 1888, until the beginning of 1889, was associated in a business capacity with a Mr. Hans Scharien, a builder and house agent, of South Kensington and Trafalgar-square. Mr. Scharien alleged that the accused received a considerable sum of money on his behalf, and that he endorsed a cheque "H. Scharien and Co." without authority and misappropriated the proceeds. Some additional charges were gone into, and accused was committed for trial to the March Assizes, all witnesses being bound over in £40 to appear.

**IN RE GREEN AND LEE.**—(London Bankruptcy Court, Jan. 27. Before Mr. Registrar Hazlitt).—The debtors, John Green and Frank Lovell Lee, carrying on an extensive business as builders and

contractors at Anton-street Works, Amherst-road, Hackney, applied to pass their examination. They attributed their failure to losses on contracts and to other causes, and the joint statement of affairs showed unsecured debts £10,985, with assets (after providing for preferential claims) £4,545. The bankrupt Green, in the course of his evidence, stated that he began business in May, 1887, in partnership with Mr. Lee. A balance-sheet was then taken, which showed his capital to be £3,554, and that of Lee £2,000. Lee also paid £1,000 premium, and subsequently brought in £1,000 additional capital, and they filed their petition in November, 1889, the deficiency upon the trading then amounting to £6,400. Mr. Clayton, for the Trustee: So that during a trading which extended over two years and five months you lost £13,000. The bankrupt Green said he attributed his losses mainly to excess of expenditure over profit, and to unprofitable contracts. The firm sometimes tendered for contracts at prices below the estimates made by their clerks. They entered into a contract for £35,000 in South Audley-street, and incurred a loss of £3,000 upon it. If he had followed the figures of his estimating clerks he would have made a profit, but he reviewed the figures and struck off a percentage, and a loss ensued. Difficulties also arose in carrying out the contract, owing to their having to do the work piecemeal, and also to delay in the delivery of terracotta. On a Langham-street contract a loss arose of £890. His private expenditure had amounted to between £1,600 and £1,700. The debtor Lee was also examined, and stated that he had lost £4,000 of his own money in the business. Mr. Registrar Hazlitt allowed the debtors to pass their examinations.

## CHIPS.

Mr. J. M. Gething, architect and surveyor, of Kidderminster and Stourbridge, has been appointed architect for the proposed free library at Kidderminster, the adjoining schools of science and art having been erected from his designs.

Mr. George Pearson, builder, of Ross, Herefordshire, died last week at the age of 67 years. He was one of the leading contractors in the county and carried out, some years since, the restoration of Ross parish church.

The Evesham rural sanitary authority has called in Mr. J. E. Wilcox, C.E., of Birmingham, to report as to the best means of obtaining an adequate supply of pure and wholesome water for South Littleton.

An examination of candidates for registration by the Plumbers' Company has been held at Bristol, under the auspices of the district council, when only 20 per cent. of the candidates succeeded in satisfying the examiners.

Sketch plans for a working men's institute to be erected in Fore-street, Lostwithiel, on a site given by Lord Robartes, were submitted by the architect, Mr. A. E. Skentelbery, of Lostwithiel, last week, and were adopted by the committee.

At a meeting held at Trinity College Lodge, Cambridge, on Wednesday, it was decided to commission Mr. W. B. Richmond, A.R.A., to execute a portrait of the late Dr. Lightfoot, Bishop of Durham, to be hung in the hall of Trinity College as a memorial.

The commissioners having urged the necessity of enlarging the Joint Counties Asylum at Abergavenny to provide infirmary accommodation in the male department, the committee at their last meeting appointed Mr. Alfred Swash, M.S.A., of Newport, Mon., as architect for the contemplated additions.

The Vyrnwy water supply committee of the Liverpool district have decided to make a complete rearrangement of the staff. After the completion of the Vyrnwy works Mr. Joseph Parry, at present assistant water engineer, will be promoted to the position of engineer and supervisor of the new works, at a salary of £850 a year, and Mr. G. F. Deacon, the present water engineer, will be appointed the consulting water engineer, receiving an annual fee of £500, and a sum of £1,750 for his services during the current year; while Mr. A. Duncanson, the deputy water engineer, will also assist in the management of the Vyrnwy works with Mr. Parry, receiving a salary of £500 yearly.

A visit was paid on Friday to the studio of Mr. John Rhind, sculptor, Cambridge-street, Edinburgh, by a sub-committee of the Lord Provost's Committee of that city, in order to inspect the model in clay of the statue of the late Dr. Chambers. The figure is 11ft. high, and is draped in civic robes. The committee expressed themselves as well satisfied with the statue, which will be immediately cast in plaster, and sent off to London for reproduction in bronze. The pedestal will be mainly of red sandstone, with four panels on the plinth containing symbolical figures. The statue will be ready for inauguration in the course of the summer.

## WATER SUPPLY AND SANITARY MATTERS.

**EAST MOLESEY.**—A Local Government Board inquiry was held on Thursday and Monday at East Molesey, before Major-General C. Phipps Carey, R.E., into the application by the Local Board of East Molesey for leave to borrow £19,000 for carrying out a system of drainage in the district. The scheme, which has been prepared by Mr. J. C. Melliss, C.E., proposes to drain the area by a system of chemical deodorisation and precipitation coupled with downward filtration through specially prepared land. Two systems of sewers will be necessary, a high and a low level, the sewage being lifted underground by means of Shone's automatic ejectors in order to save the erection of unsightly pumping stations. It is proposed to deal with the sewage in the neighbouring district of West Molesey, the residents of which strongly object to bringing into their district the drainage from other areas. The scheme is also opposed by the rural sanitary authority and the West Molesey School Board.

**VYRWY WATERWORKS FOR LIVERPOOL.**—THE OSWESTRY RESERVOIR.—Another stage in the completion of the new Liverpool waterworks has now been reached. The great reservoir at Oswestry has now attained the overflow level, and contains, according to the estimate by Mr. G. F. Deacon, the engineer, of its capacity, 46,112,000 gallons of water. The reservoir is situated about a mile and a half from Oswestry, in the natural basin below Orley Hall. The water from Lake Vyrnwy is entering it through the tunnel, nearly a mile long. It is bounded on its south and south-east side by an embankment, about 500 yards in length. Between this reservoir and the town of Oswestry are a series of filter beds (the largest ever erected), the clear-water tank, receiving chamber, buildings, and other works, the contract for which, amounting to about £70,000, has been carried out by Messrs. Davies Bros., of Wrexham. The works will be opened in the course of next summer.

On Sunday special services were conducted in St. Mark's Church, Peterborough, dedicatory of the large addition which has been made to the west end. The new narthex opens into the main body of the church by three large Gothic arches with moulded pillars. For the present it is used as a vestry, and is cut off from the body of the church by large red curtains. It can, however, on special occasions, be used for the accommodation of worshippers, of whom it would seat 100. The cost has been about £600. The architect is Mr. H. M. Townsend, and Mr. John Thompson is the builder.

The Local Government Board has sanctioned a scheme for a large extension of the outfall works, pumping station, and main drainage of the borough of West Ham, as designed by the borough engineer, Mr. Lewis Angell, at a cost of nearly £100,000. The original system of drainage was laid out by Sir Robert Rawlinson in 1860, also at a cost of nearly £100,000, and much added to since; but so great has been the development of the district that it has been found necessary to practically reconstruct the sewerage system.

A three-light memorial window in memory of the late G. B. Hanbury was fixed in St. Nicholas Church, Hereford, during last week. In the side lights are representations of St. John and St. Luke, the central light representing Our Saviour's Ascension. There is likewise a reredos in carved oak, with richly illuminated panels fixed beneath. The window has just been placed at the expense of Mr. Hanbury's friends and patients, and the reredos is the gift of his widow. Both memorials were designed and executed by Messrs. Cox, Sons, Buckley, and Co., 29, Southampton-street, Strand, London.

The first sod of the Holsworthy and Bude Railway was cut on Friday at Bude. The total length is just under ten miles, and the railway will descend from an altitude of 491ft. at Holsworthy nearly to the sea level at Bude. The authorised capital is £160,000. Mr. Fairbank, the contractor, undertakes to complete the line by 1891. Few engineering difficulties present themselves, the chief being the Stratton Viaduct, which will be 220 yards long and 80ft. high. The new railway will complete the route from London to Bude.

A large roller flour-mill has been erected in Morpeth for Messrs. R. Oliver and Sons. The architects were Messrs. Boulds and Hardy, of Morpeth and Blyth, under whose personal supervision the buildings have been erected.

Mr. F. H. Andrews, a former pupil of the Birkbeck Institute, has been appointed Vice-Principal of the Mayo College of Art at Lahore.

In the senate hall of Edinburgh University on Friday Dr. Campbell Fraser, for the past thirty years Professor of Logic and Metaphysics in the University, was presented with his portrait, painted by Mr. George Reid, R.S.A.

## Our Office Table.

WE regret to record the death of Mr. Edward William Stephens, F.R.I.B.A., of Maidstone, which event occurred on Thursday, Jan. 30th, at his residence, Sittingbourne-road, in that town. Mr. Stephens, who was in his 56th year, had suffered some time from an internal complaint. He was the third son of Mr. John Cribb Stephens, for many years a solicitor in Maidstone, and who filled the office of Mayor in 1859. Among Mr. Stephens's principal works in Maidstone are St. Faith's Church, St. Paul's Church, St. Philip's Church (tower and restoration), King-street Congregational Church, a new church at Burham, the Maidstone Grammar School, the Maidstone Girls' Grammar School, the Maidstone Church Institute, schools at Burham, Halling, and Aylesford, Messrs. West and Wright's mill at Maidstone, the Medway Brewery at Maidstone, the Nurses' Home in connection with the West Kent Hospital, Maidstone, and many private houses in all parts of the town. Mr. Stephens, together with a former partner, the late Mr. Peck, is more widely known as a joint architect of the Agricultural Hall, Islington, and he won, in open competition, the award for the design for the proposed Maidstone Lunatic Asylum, work, however, which was not carried out, owing to the passing of the Local Government Act. Another undertaking executed by the firm of Peck and Stephens was the laying out of the Maidstone Cemetery. At Cambridge, several well-known buildings were erected from Mr. Stephens's designs. He became a Fellow of the Institute of Architects ten years since. The deceased leaves a widow, but no family.

THE Bridges Committee of the London County Council having considered the report of Mr. Wolfe Barry, engineer, on the Blackwall tunnel scheme, have made their report to the members of the Council. They recommend that body to proceed with the construction of a tunnel for vehicular and foot traffic on the lines laid down by Sir Joseph Bazalgette, engineer to the late Metropolitan Board of Works. The subway, which, in the event of the Council at its meeting on Tuesday next adopting the report of the committee, will be almost immediately put in hand, will be open night and day, and will pass under the river from Poplar to Blackwall Point, East Greenwich. The Council have already expended several thousands of pounds in purchasing land for the purposes of the approaches. Mr. Wolfe Barry, in his report, pointed out the difficulties in the way of constructing such a tunnel on account of the nature of the bed of the river, and of its close proximity to the top of the subway. He considers, however, that the scheme is practicable, and in that opinion he is supported by such eminent engineers as Sir Frederick Bramwell, Mr. B. Baker, as well as by Sir J. Bazalgette. The cost of the tunnel, for which Londoners east of London Bridge have been agitating for many years, will be about a million and a half of money, and it is calculated that its construction will permanently benefit over a million people on both sides of the river.

At the seventy-seventh annual meeting of the Newcastle Society of Antiquaries a sharp discussion arose on the reading of a letter from the Rev. I. W. Milner, vicar of St. John's Church, Newcastle, demanding that the piscina which belonged to the church, and which was in Newcastle Castle, be restored to them. Mr. Milner pointed out that such property could not be sold or given away, and therefore the society could not have legal possession of it. It was the intention of the churchwardens and vicar to replace the piscina in the church if it was given back. The secretary to the society admitted that the piscina was given to them during the restoration of St. John's Church; but one of the by-laws forbade the society from giving away any of its possessions unless they were duplicated. Canon Franklin moved that the piscina be given back, observing that it was virtually stolen property. Canon Hicks seconded the motion; but Mr. C. C. Hodges said the proposal opened a very large question. The destruction that had gone on in the churches through the action of vicars and churchwardens was sufficient to make their hair turn on end. If church authorities would throw things out of the churches, they should not ask for them back again. They had no right to the

piscina. The contractor for the work of restoration would be entitled to the old material; he could give it away, and the churchwardens, in signing the contract, gave up their right to it. The piscina was worth very little, but he objected to its restoration on principle. After a heated discussion the matter was adjourned for a month, and the secretary was instructed to write to Mr. Milner asking for evidence that the piscina ever belonged to his church.

THE fifth annual report of the National Footpath Preservation Society shows steady progress. 106 new members were enrolled during the year, the total number being now 623, and the number of public bodies affiliated to the society has increased from 63 to 75. The income also has risen from £206 to £241, but even now does not meet all the necessary expenses, although the outlay does not increase with the membership. Some 94 cases of footpath stopping and encroachments were made known to the officials of the society during the year, and the Secretary, Mr. Henry Allnutt, has visited and inspected several localities where public rights of way were alleged to have been interfered with. As the Committee very pertinently remark, the advantage of such a society cannot in all cases be openly seen; doubtless its influence has prevented many attempts to close footpaths, and it is becoming known throughout the length and breadth of the land that encroachments on highways will no longer be tolerated. In many instances the sending of the society's prospectus to a gentleman of whom complaints have reached the office has had the desired effect.

THE street pavings of the Metropolis, though less noisy and shaky than they once were, when granite pitching was common, are yet anything but satisfactory during damp and slippery weather. Why cannot the City Commissioners and the vestries combine together to introduce some kind of paving which will give a good foothold to horses, who are now constantly falling down just at those points where the inclination of the roadway is steep? The cost would be trifling of laying down in these situations blocks of asphalt or concrete having corrugations cast on them.

At Nashville, Tenn., bricks are used creosoted, prepared by saturating common kiln bricks of hard quality with liquid pitch. They are laid on a foundation of rolled macadam, and bedded on edge in sand and then rammed. Roads of this material have lasted four or five years under considerable traffic, and show little wear. At Alleghany city it is stated fireclay bricks have been laid in two layers on rammed and rolled gravel and sand. The pavement has been in use some years under heavy traffic, and is stated to be very smooth and easily cleaned. Many other cities of the Union have brick pavements, after giving up macadam and wood.

THE annual general meeting of the Geologists' Association will be held at University College, Gower-street, to-day (Friday), at 7.30 p.m., when the president, Mr. T. V. Holmes, will deliver an address entitled "Notes on the Nature of the Geological Record." Dr. Johnston Lavis is preparing a report of the excursion of the association last autumn to the volcanic regions of Southern Italy. It will contain contributions from the eminent Italian geologists who guided the party, and will be illustrated with maps and plates.

## Trade News.

### WAGES MOVEMENTS.

BARNSELY.—During the last week several classes of builders' workmen in the neighbourhood of Barnsley have decided to take action in the matter of wages. The masons of the town and district have given notice to their employers of an intention to demand an advance of 1d. per hour, and it is expected that the bricklayers will take similar action. The carpenters and joiners had a meeting, and also decided to go in for an advance of 1d. per hour, making in each case a total of 8d. per hour; and the painters of the town have had the same question under consideration; but they have no society, and have been unable to come to any decision.

BRISTOL MASTER BUILDERS' ASSOCIATION.—The annual report for the year ending December last states that during the past year the association has been reorganised, which promises materially to improve its prospects. There is every indication that the accession in the number of its members, which

now practically include all the master builders of this city and district, will tend to develop its work. The unfortunate disputes which have arisen between capital and labour during the year have engaged attention; but the members, and also their employes, must be congratulated upon the amicable relationship that exists between both parties. The men have not been avaricious in their requests, neither have they threatened or resorted to strikes. From time to time a sub-committee communicated and conferred with several of the labour representatives upon the question of an advance of wages in the respective departments of the building trade, and the men, in consideration of many heavy contracts that members were engaged in, readily accepted the decision of the association—that an increase of 1d. per hour in all branches of the trade should take place on 28th March next. The members have had under consideration the manner in which tenders are received and opened at some architects' offices, much dissatisfaction having been expressed in relation thereto, and a suggestion was made that if architects would appoint a time and place for opening such tenders, members tendering would make it a point to be in attendance. The association have been contending for some time past for an arbitration clause in all forms of contract, and it is to be hoped that every member will endeavour to obtain the insertion of such a clause in future contracts. Notwithstanding the strikes and rumours of strikes in many sections of trade and commerce, there has been a thorough revival in trade throughout the country.

NEWCASTLE-ON-TYNE.—A notice issued on Monday by the Tyne District United Trades Committee to the employers in the house building trade in Newcastle and Gateshead, giving notice on behalf of the joiners for an advance of one penny per hour upon the present rate of wages, and overtime in proportion, to take effect on and after the 1st March.

KIRKCALDY.—The whole of the operative masons in the Kirkcaldy district struck work on Monday in consequence of the employers having refused to increase wages an additional halfpenny per hour. The trade is exceptionally busy, and men have hitherto been paid 6d. per hour.

### MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Clerks of Works Association. Annual dinner. Holborn Restaurant. 6.30 p.m.  
Royal Academy. "Roman Architecture," No. 5, by Prof. Geo. Aitchison, A.R.A. 8 p.m.  
Society of Arts. "The Electro-Magnet," Cantor Lecture No. 4, by Silvanus P. Thompson. 8 p.m.  
Surveyors' Institution. "Suggested Amendments in the Law and Practice of Compensations," by G. M. Freeman. 8 p.m.

TUESDAY.—Society of Architects. "Twenty-five Years of Architectural Progress," by James Hicks, of Redruth, Vice-president. 7.30 p.m.  
Society of Arts. "Cast Iron and its Treatment for Artistic Purposes," by W. R. Lethaby. 8 p.m.  
Institution of Civil Engineers. Discussion on "Bars at the Mouths of Tidal Estuaries." 8 p.m.

WEDNESDAY.—Carpenters' Hall Free Lectures. "Drawing—Geometrical and Perspective," by Prof. T. Roger Smith, F.R.I.B.A. 8 p.m.  
Society of Arts. "Modern Improvements in Facilities for Railway Traveling," by G. Findlay, General Manager L. and N.W. Railway Company. 8 p.m.

THURSDAY.—Royal Academy. "Roman Architecture," No. 6, by Prof. Geo. Aitchison, A.R.A. 8 p.m.]

FRIDAY.—Architectural Association. "Some Typical Greek Buildings," by R. Elsey Smith. 7.30 p.m.

Bradford Historical and Antiquarian Society. "The Pilgrimage of Grace," by J. Lister, M.A.  
Royal Institution. "Problems in Physics of an Electric Lamp," by Prof. J. A. Fleming, M.A., D.Sc. 9 p.m.

Architectural Association, 9, Conduit-street, W.—February 14, "An Account of some Typical Greek Buildings," by R. Elsey Smith, Esq. 7.30 p.m.

## WORKING DRAWINGS AND THEIR INTERPRETATION.

THE interpretation of drawings by artificers connected with building will be necessarily imperfect till the art is made one of the acquirements of the workman. In England the subject has never been brought down to the level of the workman's knowledge, and only of late years has there been any attempt to teach drawing to workmen in a systematic manner. The technical schools in France and Germany have long made drawing an essential mode of training the eye and hand. Every trade has to pass through the stages of drawing. Copying from paper examples is forbidden in some schools, and the system is to get the pupil to draw from models, so as to teach him to apprehend the meaning of lines in perspective, as well as to make him understand geometrical delineations. In our opinion drawing can only be properly taught by the aid of models, and a course of well-directed model drawing will do more to instruct the eye and mind than all the flat copies and diagrams of the textbooks. Professor T. Roger Smith's useful and suggestive lecture on "Drawing" at Carpenters' Hall, reported in full in our issue of to-day, presented the subject in the most lucid manner, and as an elementary exposition of the principles of geometrical and perspective drawing, it could hardly fail to draw the attention of the practical audience. Professor Roger Smith made a strong point of the value of drawing to the working man. "Every difficult piece of construction is worked out on paper," even our contracts and estimates are made on the basis of plans and drawings. The interpretation of working drawings is one of the things wherein the English workman is deficient or imperfectly instructed. We have even known otherwise good bricklayers and joiners, unable to read without some study and time a detail drawing, whereas the first sight of the drawing should be enough to enable the workman to grasp the general meaning of the design intended to be conveyed. To many artificers technical details are like a foreign language: they have to be interpreted by the foreman or clerk of works, or set out full size before they can be rightly understood. The instructive paper of Professor Smith put the subject before the workman in a very intelligible and familiar manner. Nothing was taken for granted—even the meaning attached to the term "geometrical" was clearly explained as representing the building "as it actually is," not as it appears to the eye. We have occasionally met with building tradesmen, and even small builders, who have a very confused idea of the distinction between a perspective and a geometrical elevation, and have even seen drawings made by them which represent both sides of the building or feature at once, though too ill-drawn to be taken as perspectives. Many useful remarks were made by the professor on the necessity of exactness, and the importance of a scale, which should be both described as well as drawn. Some workmen can understand the description of an "eighth scale" or "8ft. to the inch," but they cannot correctly take any distance from the drawn scale; and many, on the other hand, can use a drawn scale who cannot understand or read the description in writing. We quite agree with the remark that the most familiar scales should be used—such as 16ft. to the inch, 8ft. to the inch, 4ft. to the inch

—for general contract drawings; and that those divisions of the inch like tenths and twelfths that are less common tend to confuse. The value of the  $\frac{1}{2}$  in. scale is pointed out. No doubt that it, and the  $\frac{1}{4}$  in. to the foot, and the 3 in. to the foot, or the quarter full size, are the most desirable scales for detail drawings. The half full-size is certainly objectionable, and should never be employed, as it is too nearly the full size, and is very likely to misrepresent the actual results. The figuring of dimensions is another point to which reference was made. Dimensions to be useful ought to be scrupulously accurate, or they are worse than useless. The figuring of plans is done often without much system. If centres of openings or pilasters are taken, the method should be strictly adhered to throughout. Dimensions taken to the jambs of openings, and the width of openings, are generally adopted by draughtsmen; but unless there has been great care in making these detailed dimensions closely agree with the extreme length, the other method is less liable to lead to error. For the practical business of setting out buildings, we think the method of measuring solids and widths of apertures is the best, taking care to check accurately the equal division of windows or piers by the axial method. For instance, in setting out the plan of a church, the dimensions should not only be given between the buttresses, but be figured to their centres; there should be, in fact, two sets of dimensions—one giving the widths of piers and openings, the other set the distances between centres. Much confusion and many mistakes arise by depending too much on the separate or detail dimensions, and the figuring of wall thicknesses—a source of trouble to those who are not in the habit of checking the dimensions before the building is set out. The architectural draughtsman, as Professor Roger Smith says, likes to avoid a difficulty rather than attack it, and in making a drawing, if he has not got the information in his head, he cannot put it on the paper. We are inclined to think the ordinary draughtsman is apt to leave the headwork for others, and is tempted to pay more attention to the mechanical fineness and neatness of his drawing than to overcome difficulties as they occur. If he does not know, he could find out, as the lecturer says, but the labour of inquiry is uncongenial. Let us suppose something new is to be designed or drawn—say a cabmen's shelter. The competent designer makes his drawings only after the facts and data of his requirements have been obtained and thoroughly digested in his mind; the ignorant draughtsman draws without knowledge or facts, relying upon after-correction, and his plans are crude, and meet the requirements imperfectly. As for solution of difficulties, he does not trouble himself about them: he draws something that pleases him, and which he thinks will suit the purpose—it is not a drawing from knowledge, but a mechanical piece of penmanship. The most useful kind of drawing for workmen is that in which solids and sections of solids are concerned; simple projection is far more necessary than perspective, and therefore it is that we place model drawing in the foremost place. Some acquaintance with geometry is absolutely essential to a successful course of instruction. We admit that the textbook courses repel rather than invite: the exceedingly dry and abstract definitions of lines and planes are discouraging. We wonder when instructors of drawing for technical classes will see the importance of beginning their courses with concrete embodiments of form—such as taking the plans, elevations, and sections of a plain building—teaching the principles of projection, together with freehand model drawing, before descriptive geometry and perspective are thrust upon the beginner.

## ARCHITECTS' CERTIFICATES.

THE power of giving or withholding a certificate under a building contract invests the architect with an authority not easily disputed, though exceptional circumstances happening, it may place him in not a very enviable position; as when, for example, he has unknowingly given a certificate to a builder before the latter is properly entitled to receive one, and has thus placed his employer and himself in very awkward circumstances, should they find themselves compelled to call upon the builder to complete his work to their satisfaction. The extreme importance of being guided by personal examination of the progress and completeness of the work, whatever it may be, cannot be too strongly enforced on the architect. When a responsible clerk of works is engaged, the weekly or monthly reports sent in may be accepted; but when the architect is the sole judge of the value of the work executed, it is always an injudicious course to give a certificate from a bare recollection of the condition of the building. Certificates are of two kinds, intermediate and final; the former may be called "progress certificates," and are those which are given at intervals to the contractor as statements of the value of materials in the buildings and on the site and labour; the payments or advances made under them are provisional, and subject to readjustment. It is usual in the contract to state under what conditions, or when, the contractor is to receive any certificate, though this is not always observed with the scrupulous attention it ought to be. Sometimes a contractor, if of limited means, asks for a "draw" before he is strictly entitled to receive one, in order to enable him to proceed with the work. The wages may amount to a large sum, and an advance is of the greatest convenience to him. The architect, perhaps, responds to the appeal, and in so doing oversteps discretion, and places himself at the mercy of the contractor, who being paid fully up to the value, of material and labour, or in excess of that value, can decline to proceed. Payments are generally made at the rate of 80 per cent. upon the value of works executed and materials delivered, and, as our readers know, it is usual to name a certain expenditure upon which that rate of payment is made.

At other times the sum is left to the discretion of the architect. When the difference between the percentage and the value of the work executed amounts to a certain percentage (determined in the agreement) upon the amount of contract, the contractor is paid to the full value of the work executed and not included in any former payment. When the work is completed the contractor receives one moiety of the amount remaining due according to the valuation, and the final certificate for balance is to be payable within a certain stated time after completion of the works. This mode of distributing the payments leaves the employer on the safe side: after every instalment, there is a balance due, which increases till a certain percentage is secured upon the amount of contract. On the proper adjustment of these payments the fairness of this mode of making the instalments depends, for if after a contractor has executed, say, £500 worth of work he gets more than his 80 per cent., or £400, there is a risk of making subsequent payments so close to the value that the employer gets the worst of the bargain. We know that in many cases this rate is exceeded; very often the instalment is quite equal to the value on the building and site, and when the final certificate becomes due the expectations of the contractor are far greater than he is justified in realising.

Now it is impossible to fairly adjudge the sum expended, or the value on the building unless an estimate is made as the building proceeds, including a valuation of the materials on the site which are the building owner's

property. We have several times found little contractors tamper with these materials, or remove some of them for other works near, or even to their own premises for reuse: hence the necessity for the clerk of works or surveyor seeing that these materials are not touched, and that their value is ascertained as part of the valuation for a certificate. Valuations for this purpose are often of a rough kind, allowable in some cases where the building is a plain one, but unreliable when a quantity of different kinds of labour are involved. We have, for example, seen an approximate estimate made of the works—a sort of rough “quantities,” in which process, instead of analysing everything, as it is proper to do on accurately prepared quantities, the valuer lumps the items, by taking all the labours involved in one kind of work, such as brickwork, by including the items of facing, arches, &c., carpenters’ work, such as a roof, by making the value inclusive of every part of a roof, the slating as well as the timbering. Thus, a square of flooring or roofing would be valued complete, inclusive of every item connected with it; each window would be taken to include labour of reveals, sash and frame, glazing and painting, and in this manner a fairly approximate value of the work executed may be gained. Even the rougher plan of cubing has been resorted to for the purpose of a certificate—a very risky mode, and liable to considerable error. But, for works in progress, the clerk of works can adopt a readier method of finding out whether a certain amount of material and labour has been expended. He can measure the work as it proceeds at certain stages, especially those parts which are concealed; the variations which may be made as the building goes on are open to him, and should be measured in conjunction with the builders’ foreman, the dimensions being mutually agreed to. These dimensions are booked, and can be referred to at any moment, and a fairly approximate valuation made. Therefore little difficulty ought to be found in estimating the actual expenditure on a building at any given time, or when the contractor applies for a payment.

Disagreements between contractor and architect do not generally arise out of interim certificates, but often at the completion of the work on the giving of the final certificate. Suppose we consider a case where extras have been ordered, though the builder has not, as he should have done, obtained a written order for the work in accordance with the contract agreement. The building is proceeded with, and at the completion of the work the contractor hands in the statement of his account to the architect, who, after verifying it, includes it in his final certificate to the contractor. The employers decline to pay the extra charge because the contractor had not produced the order in writing as required by deed. The legal opinion of the matter has been expressed clearly in one case, that the certificate of the architect is conclusive and final, and the defendant is precluded from setting up as a defence that the extra work had not been ordered in writing.

An important decision as to whether, after certificates for a balance arising out of contract and also for additional works had been given to a contractor, the employers could refuse to make payment on them on the plea that the prices were too high, and there were penalties for delay against the contractor, was given in the Queen’s Bench Division in 1885, the defendant employers being the Isle of Wight Sanatorium Company. It was an appeal against a decision by a judge at Chambers to defend the action. The architect had given certificates for balance and for other works out of the contract; but differences arose between the parties. The contractor brought an action to recover balance due on the certificates, he contending, on the principle already stated, that as the

architect had given certificates, he was entitled to recover. The defendant company denied their indebtedness on the ground that the prices were too high, and that, owing to delay, there was little due. But the defendants never objected to the certificates being given; and it was further argued by the counsel for plaintiff that there was nothing to decide, as the certificates were final, and that there could be no defence against the architect’s certificates. Mr. Justice Grove and Mr. Baron Huddleston both heard the case, and a contention arose as to a clause in the contract that, in case of dispute, the architect’s decision was to be final. It was contended that the dispute between the parties was decided by the architect’s certificates. Baron Huddleston concurred in this view, and said that “it appeared to be an answer to the argument that the arbitrator is to decide any disputes between the parties,” whereas the defendants had never raised a dispute by objecting to the certificates. This case indeed appears to confirm the general idea that an architect’s certificate is conclusive, though the judges differed in opinion as to whether the defendant ought to have leave to defend. When there is a contract provision that the arbitrator is to decide any dispute, and the arbitrator (in this case the architect) makes a certificate for the amount, it is somewhat unreasonable to require the question to be referred to him again for a decision, as he must uphold his own certificate. Here the defendants had made payment on account, and had so far admitted their indebtedness, and, therefore, there is a strong presumption that the above view was the correct one. Justice Blackburn’s judgment in the case of “Wadsworth v. Smith” is important in this connection, and may be quoted, as he there points to the difference between agreements as to a certificate, and those in reference to any dispute. He there briefly observes: Where, by an agreement, the right of one party is made to depend on the determination of a third person, it is not a submission to arbitration; but where there is an agreement that any dispute about a particular thing shall be inquired into and determined by a person named, that may amount to a submission to arbitration, and the determination, though in the form of a certificate, be an award.

The arbitration provision ought certainly to make it possible to correct any mistake in certifying a larger sum than is really due, and if an arbitrator be appointed other than the architect, there would be no difficulty in doing so; but when the architect is arbitrator, his final certificate certainly makes it impossible to reopen any question of dispute that may arise. We have cited the above case to show the caution there should be taken in granting final certificates, especially when the provision for questions of dispute are referred to the architect himself, as in that case he may unwittingly be doing an injustice to his employers if it should turn out that, owing to delay in completion, or other evidence of overcharge for additional work, they had no means open to them of correcting a mistake or of being heard in defence. From the often-quoted case of “Goodyear v. Mayor of Weymouth,” an architect’s final certificate allowing extra work supersedes all written orders for extras, pointing to the importance of rigidly enforcing the usual clause for extra works to be ordered in writing. Irregularities occur in the giving of certificates. A correspondent refers to a case where an architect sends a final certificate to his client instead of to the contractor. The client wishes the architect to reduce the amount, which he does. The contractor naturally complains of the treatment, and is in a position to bring an action if he can prove that the architect has been indiscreet or unfair in giving a certificate so that he is thereby a loser. In such

a case it is necessary to prove a collusion between the architect and employer. Again, if it can be proved that the architect has, in collusion with the employer, withheld his certificate, though the amount is fairly due to the builder, the latter has the right of enforcing his claim against the architect. The case of “Ludbrooke v. Barrett” is in point. The certificate that the builder had executed the work satisfactorily was withheld by the architect, in collusion with the employer, and the builder sued the architect for damages.

#### BRICKS AND BRICKMAKING MACHINERY.

By M. POWIS BALE, M.Inst.M.E.; A.M.Inst.C.E.  
Author of “Woodworking Machinery,” “A Handbook for Steam Users,” &c.

IT is not our intention here to deal with the constructive details of a brick-moulding machine, but it may not be out of place to mention a few of the points to be desired in one. As regards design, the chief points to be aimed at are strength, simplicity, and durability of the working parts, combined with effective production. Complicated machines, which may be theoretically perfect, are often subject to frequent breakdowns, and are quite unsuited to the rough usage of a brickfield. The larger machines should, in all cases, be mounted on a substantial foundation plate or base to withstand the various racking strains in working.

All the bearings and working parts should be protected from grit and dirt as much as possible, yet they must be readily accessible for adjustment, repairs, and renewals. The bearings and working parts should be made adjustable for wear where possible, and if a little increased cost is not an object, phosphor-bronze can be recommended for bearings. When subject to great strain or pressure, these should be of increased length to distribute it as far as may be. Gear-wheels should be very carefully moulded and fitted, or the friction and consequent driving power will be largely increased.

If crushing rollers are used, they should be of very hard chilled metal, readily adjustable for wear and to suit the nature of the clay being worked. The side frames should be of massive construction, well braced together, and a safety appliance fitted to relieve the rollers and prevent breakage, should iron or unbreakable material get between them. Steel can be recommended for pug-mill and other shafts, and either multiple collar or roller bearings to receive back thrust can be fitted with advantage when the duty is severe. As elsewhere remarked, in lieu of single shafts, double shafts and blades have been introduced into pug-mills, and it is claimed for this arrangement that greater homogeneousness in the clay is obtained.

Our illustration, Fig. 6, represents a three-process brick-moulding machine for plastic clay, from the designs of Messrs. Clayton, Howlett, and Venables, Harrow-road, London, who have had large experience in this class of machinery. It combines in itself the operations of crushing, pugging, and moulding, and is particularly suitable for strong clays that do not readily weather or take up much water. As will be seen from the sketch, the working parts are mounted on a box bed-plate to secure rigidity in working. The crushing rolls and pug mill are driven by powerful toothed gearing; the former are placed at the top of the machine, and not only crush the clay, but force it into the pug-mill. The pug-mill shaft is fitted with knives and screw-blades for mixing the clay and forcing it through the die. The important features claimed for this machine are the methods of constructing and operating the brick dies and cutting table, and these we propose to illustrate and describe separately. In addition to solid bricks, with a little alteration these machines will make perforated and tubular bricks, copings, drain-pipes, &c., at a speed of from 10,000 to 30,000 per day, according to the size of the machine.

#### BRICKMAKING MACHINE DIES, ETC

Although apparently of a simple nature, there is little doubt that one of the most critical points in the construction of a brickmaking machine is found in the dies and compressing chamber through which the clay is forced, and much ingenuity has been expended in trying to devise

FIG. 6.

a die that will permit a steady stream of clay, perfect in shape, and of any nature, to pass through it. In moulding bricks singly by hand or by hand-power machine this difficulty is not so severely felt, although considerable skill must be exercised by the hand-moulder in filling the mould completely in all its corners. Hand moulds or dies are usually made of wood, either plain or lined with polished brass or steel plates, the object desired being that the brick shall leave the mould with as little friction and of as perfect a shape as possible. With some plastic clays of moderate tenacity little difficulty is found; but in the manufacture of London

stocks, which contain chalk, ashes, &c., and are sand-moulded on the face, and with mild clays generally, the operation is not so simple as it would appear.

To try and get rid of this difficulty many plans have been devised, and one which gives every prospect of being a commercial success has recently been introduced by Messrs. Eddington and Stevenson, of Chelmsford, in conjunction with a hand-power brick-moulding machine, which we shall illustrate elsewhere. This mould, which we illustrate by Fig. 7, is arranged to open or expand after the clay is moulded, so that the brick can leave the mould in good shape

and without dragging at the corners or elsewhere, and is delivered directly on the pallet-board for immediate removal. Wood is used for lining the moulds, and can be readily renewed when worn.

Referring now to the dies used in plastic machines, in which the flow of clay through them is practically continuous, here fresh difficulties arise. Owing to the friction of the clay on the sides and angles of the die, it is found in practice that the stream of clay flows faster in the centre of the die than at its sides; to equalise the flow as far as may be, various plans of reducing the friction of the clay have been intro-

Fig. 7.

duced. One of the best known is Murray's patent. This die is not driven, but the sides and ends are made adjustable; the ends are arranged with vertical grooves and covered with fustian. The fustian is kept constantly lubricated by means of water, the supply necessary to insure an easy passage of the clay being regulated by its nature. As the die wears it can be adjusted to its original size, and the fustian easily renewed, as may be required. It is claimed for this die that mild and loamy clays can be passed through it with facility, and clean, sharp bricks produced.

With the object of equalising the speed of the clay at its centre and ends on its passage through the die, an ingenious arrangement of cheeks, compressing-chamber, and die has been patented, and introduced by Mr. J. Pinfold, of Rugby. In his invention the clay is pugged and fed forward in the usual manner by right and left-handed screw-blades to compressing rollers and a compressing-chamber consisting of that portion of the machine between the propelling mechanism and the die. It is claimed by the inventor that as the difference in the speed of the travel of the clay is not seen until it has passed the die, it has been generally concluded that the fault has been with the die itself, and the efforts of inventors have been expended in improving this; but as a matter of fact the difficulty has taken place before the clay has arrived at the die, and that it required assistance immediately after it had left the propelling mechanism. The object of the inventor has been to give that assistance; this he does through the medium of cheeks which are carried past the end of the propelling rolls and forward right up to the back of the die, and are fitted with an appliance for lubrication. In other machines where cheeks are applied they are arranged between the die and the propeller only. On turning on the water which is used for lubrication, the clay adjoining the cheeks becomes greasy or slippery, and thus the ends are eased and assisted as the clay travels towards the die, and no lubrication whatever is needed at the die itself. The inventor has found in working that a pressure of water of from 40lb. to 50lb. per square inch is necessary to overcome the pressure of clay in the back of the compressing chamber, and if a lower pressure of water is applied the cheeks will not work, owing to the pressure of clay on the lubricating orifices being greater than the water pressure. It is, therefore, usual to connect the lubricating water supply to the water space of the boiler used to drive the machinery. The die employed consists of an iron casting lined with hard wood, the inside surfaces being shaped to a definite angle, and in a peculiar form, so as to minimise the effect as much as possible of the difference of travel between the ends and middle of the stream of clay. The wood lining of the die is lined with brass, which is fitted with the lubricating portion of the die, which lubrication is applied in such a position as to aid the ends, whilst retarding the travel of the middle of the clay.

With the object of reducing the side friction of the clay on the die, Messrs. Clayton, Howlett, and Venables, of Harrow-road, London, have also introduced a rotary die. This consists briefly of a pair of large rollers, arranged vertically the length of the brick, and driven by suitable bevel gear. The top and bottom of the die are lined with brass, are stationary, and readily renewable when worn; water is used as the lubricant, and these are suitable for both plain and perforated bricks.

Although a great deal of ingenuity has been expended in making dies of various forms, none can be pronounced as the best under all circumstances, and for all kinds of clay. Mr. J. Hill, in writing on the subject, recommends a plain parallel water die made of soft wood as very effective. It is made of a depth of about 9in.

from back to front, and lined with fustian in one piece, tacked round the back of the die, and left perfectly loose towards its front. A groove is cut round the woodwork inside, about  $\frac{1}{4}$ in. wide and  $\frac{1}{4}$ in. deep, to allow the flow of the water all round the die between the wood and the fustian. It is claimed that by leaving the fustian loose, as above described, it is always perfectly smooth, and does not form creases as it does when the fustian is secured, nor does it wear out so fast. The pressure of the clay on the fustian prevents the water escaping too rapidly from the die.

#### CARPENTERS' HALL LECTURES.

##### I.—THE ARCHITECTURE OF THE WORLD IN ALL AGES.

A SERIES of six free lectures is being given on Wednesday evenings at the Hall, and under the auspices, of the Worshipful Company of Carpenters, London Wall, E.C. The first address was delivered on the 5th inst. by the Master of the Company, Mr. Banister Fletcher, J.P., D.L., F.R.I.B.A., who took as his subject "Architecture in all Ages," illustrating it by a series of nearly two hundred photographs and drawings hung on the walls, besides some diagrams lent by Professor Roger Smith. Primarily, Mr. Fletcher remarked, architecture arose from the necessity of providing a habitation for man as a protection against the climate and weather; but had it never progressed beyond this its legitimate object, it would never have risen beyond the level of building. Having quoted Viollet-le-Duc and Gwilt on the origin of human habitations, the lecturer described the rock-cut caves and temples of India, and then proceeded to sketch the various forms of architecture throughout the world, giving illustrations of the leading examples of each class and period. Beginning with Egyptian and Assyrian styles, he passed on to the Hindu, Chinese, and Mexican, returning to the Greek, Roman, and Saracenic, with its development in Syria, Persia, India, Turkey, and Spain. Thence he went on to consider the Romanesque, the Italian, and the Gothic, with examples in France, Belgium, and Great Britain. Continuing his survey of the history of the art, Mr. Fletcher pointed out that the Elizabethan style was fostered by the introduction of the features of Italian art; it consisted, indeed, of an adaptation of forms derived from a study of Roman models to the requirements of the times, occasionally mixed up with the remains of Debased Perpendicular. While it presented sometimes a somewhat incongruous appearance, it nearly always had a picturesque effect. The Elizabethan style, which was scarcely at all used in churches, of which few were built at the period, was the first introduction of Renaissance into this country. The Renaissance as afterwards developed was the designing of new buildings on the ancient forms of art, and in Italy passed through three phases—the Florentine, Modern Roman, and Venetian, each of which was described and illustrated. From Italy the style passed into France, where it was developed on the rules and principles laid down by Vignola, and at a later period was brought into England, being introduced from Italy by Inigo Jones, and carried on by Wren. Following the Renaissance at the end of the 18th century came a period of minute copyism of ancient Greek forms, a big example of which was St. Pancras Church, another the British Museum, and a third and still later specimen, Euston Terminus. The unsuitability of pure Greek buildings having been made manifest, an effort was made to escape from the thralldom of mere copying and to return to the true principles of art by designing new forms of buildings, and this led to the second revival of Renaissance.

More recently, Pugin, Street, Scott, and others had revived Gothic architecture, although we had no definite style that could be called a genuine modern or 19th-century style of architecture. In conclusion, the lecturer remarked that hitherto each new type was the outcome of some distinct impulse; but the impetus given to invention during this century by the utilisation of steam and electricity, although it created a new style in shipping, in architecture it had done practically nothing—a fact which he regarded as due to the great competition of the age, which led all to strive to turn out as great a result as possible with the smallest outlay of intellect or money.

##### II.—DRAWING: GEOMETRICAL AND PERSPECTIVE.

The second of the series of free lectures at Carpenters' Hall to members of the building trades was given on Wednesday night by Professor T. Roger Smith, F.R.I.B.A., who took, as his subject, "Drawing: Geometrical and Perspective." Drawing is becoming, he observed, more and more one of "matters relating to building." Every difficult piece of construction is worked out on paper. Our contracts are arranged, our estimates are made on the basis of plans and drawings, and these are consulted every hour during the progress of any important building, while the deposit of plans of sites, drains, and buildings, which modern laws and by-laws so often render necessary, has made it requisite to prepare copies, in duplicate or triplicate, of plans of almost every building, even the smallest. This is the case far more now than when the lecturer began to become familiar with building matters, and very far more than it can possibly have been a century back; while, before the use of paper had superseded parchment, or even before the time when paper was obtainable in large sheets, drawings were a rare luxury. No one can do much building work who cannot read a drawing with facility, while no one can hope to rise to any position of responsibility in connection with buildings who cannot make a tolerable drawing of anything that he has to deal with. Even those the nature of whose work makes it unlikely that they will be called upon to make drawings, will do well to learn to draw, in order that they may be able to understand and make use of working drawings. The phrase which I have just made use of—viz., "reading drawings," is constantly employed to explain this power of understanding drawings, and is very significant. To one man a drawing conveys information, just as a book in a language he understands will do; to another man a drawing is as much a puzzle as a book in a language which he has not learnt; and the man who cannot understand the drawings for a building is unavoidably shut out from much important employment in connection with it for which he might in other respects be quite fitted. Now, there is no way of learning to read surer than learning to write—no way of learning to read drawings surer than learning to make them. This alone ought to give draughtsmanship great importance to the members of an audience like the present. The subject naturally splits into two divisions, and I have attempted to mark them by the use of the two words, Geometrical and Perspective, in the title. Let us consider for a moment what is the nature of the distinction. I think it cannot be more tersely put than if we say that geometrical drawing represents things as they are, and not as we see them. Perspective drawing represents things as they appear to the eye, and not as they are. This sounds like a paradox, but it is the simple truth, and the paradox, and there be one, rests upon the singular circumstance that our sight, from which we derive almost all our notions of solid things, rarely, if ever, lets us see them as they are, but almost always modifies or distorts them in a manner which you will recognise the moment it is pointed out to you. Go into a great building with an open roof—say, for example, Westminster Hall, and look up at the trusses of the roof. You see them all—one beyond another—or at any rate you see a portion of each past those nearer to you, and each one as you look up at it appears below the one on this side of it, and smaller. The trusses appear to be diminished and lowered by distance, and in drawing such an interior in perspective, the draughtsman would put in each truss lower and smaller as it recedes from the eye. In real truth, however, as has just been said, the trusses are equal in size and all on a level, and were the draughtsman

showing the interior of Westminster Hall on a geometrical drawing, he would draw the trusses all of a size and all at the same level (in such a drawing as, for example, a longitudinal section). Take a geometrical elevation of St. Paul's Cathedral, and look at the relative positions of the great west portico and the dome. The geometrical elevation will show you what is the fact: that the dome is exactly behind the portico, so that a line which divides the portico into two halves, and cuts through the apex of the pediment, if produced, would divide the dome into two halves. Go to the building itself, and you will find that though when you are exactly opposite the two features are in the same relation to one another, the moment you move to the right the dome appears to move to the right also, and the apex, or point of the pediment, begins at once to move towards the left of the dome, so that a person taking a view of the cathedral from a point where the front and flank are both visible—for example, from the S.W. angle of the churchyard—must represent it, with this pediment towards the left and the dome towards the right. Perspective drawings then mean drawings of objects as the eye sees them, including, if you will, other things than buildings, though to buildings we shall chiefly confine our attention. Geometrical drawings mean diagrams which represent the actual shapes and arrangement of things, but represent them as we never exactly see them, but only as we know them to be—just in the same way as a map represents a country, a town or an estate—not as we see it from some neighbouring eminence, but mapped out to scale. The foundation of all geometrical drawing is the use of a scale and the power of measurement. Take the simplest and most familiar case—the ground plan of a house. Here you have what may very well be described as a map of the floor and walls exactly as they are to be, but as it is never possible to see them. Supposing this to be drawn to an eighth scale—i.e., a scale of an eighth of an inch to one foot, then the value and usefulness of the plan depend chiefly—I may say entirely—upon the dimensions of every part of it being exactly one ninety-sixth of the dimensions of the corresponding part of the building or intended building. You want to know how thick a wall is to be, you find it drawn a quarter of an inch thick, and you multiply that dimension by 96 (or more correctly, you perform the simple process of measuring with a scale, which is equivalent to multiplying by 96, without trouble), and you find that your wall is to be 2ft. thick. When you have once decided on your scale, you have to make use of it while drawing your plan, as you are to make use of your 2ft. rule, or your rods, or your tape on the real building, and when your plan is about to be carried into execution, you make the same use of the scale to inform you what to set out on the work. This, which may seem too obvious to need stating to some of you, but which could not quite be passed over or taken for granted, is the foundation upon which the whole system of geometrical drawings for builders rests; and, in actual practice, one cannot be too careful about having every part of every geometrical drawing correct to scale. If you fail in that, you fail at the outset. The next thing to point out is that it is only possible to show one aspect of the object illustrated in one geometrical drawing. In our view of St. Paul's Cathedral from the south-west, you see at once a glimpse part of the front and part of the flank. To give you some notion of this geometrical drawing you would require three drawings—a front elevation, a side elevation, and a plan. From this limitation of geometrical drawings to one aspect only in one drawing arises the need of the three sorts of drawings which are in common use in connection with buildings—plans, elevations, sections. A plan is a diagram or drawing to scale of one of the floors of a building or of its roof, showing also the inclosing walls and the openings in those walls. An elevation is a diagram or drawing to scale of the outer face of one of the walls of a building. A section is a similar drawing of one of the inner faces of the wall of a building, showing along with it the level of floors, the construction of roofs, and the depth of foundations. It is made by assuming an arbitrary line from front to back or from side to side, and imagining the building to be cut through on that line, and then putting into the drawing elevations of all those parts which would be disclosed by such an operation, while those portions which would be actually cut through are tinted or lined so as to make them dark, just

as the walls on a ground plan are tinted. These three sorts of drawing—plans, elevations, and sections—are all requisite if a building is to be shown with anything approaching completeness, and usually in a building of any size several of each sort are required as—e.g., a plan of each floor and of the roof, an elevation of each external face, and at least two sections. A fourth sort of drawings is also required on any building that is at all complicated—namely, detail drawings. These are to a large scale, and the more intricate the construction, or the more elaborate the work, the more numerous and important will they become. Detail drawings to elucidate important parts are partial plans, elevations, or sections, or often all three grouped on one sheet, drawn to a bold scale, or even full size, and representing a small part only of a building. Going back to my account of geometrical drawings—namely, that they correctly represent the building or the part of the building which they depict not as it appears, but as it actually is—it arises that it is of great importance when designs are being made that the shapes selected shall be good, the proportions pleasing, the forms well chosen; for upon this it really depends whether the work shall be satisfactory in appearance or no. A geometrical drawing gives a good clue to the real nature, and therefore to the appearance, of the future building, even though it does not represent it as it will be seen. If your drawing looks ungainly, so will the building. If the proportions of your building are to be right, let there be definite relations between the parts of your plan, and section, and elevation. It should, therefore, be part of a draughtsman's care in preparing drawings to be built from, that these drawings, which represent the exterior or interior—in other words, his elevations and sections—look as like as possible to the intended building. This, I assure you, is a most necessary thing to keep in mind. Drawings are far more often than not so got up as to present an appearance very different from that of a proposed building. They are often, intentionally or unintentionally, very deceptive. Little flat pilasters are drawn as if they were strong, bold columns, throwing a great, well-marked shadow; blank windows which will be executed as panels are coloured so as to look just like adjoining windows; materials that are of contrasted colours are drawn as if they were all uniform—or, on the other hand, materials of one colour are shown as if there was a contrast. In these and a score of ways many showy drawings are deceptive, and this practice is very much to be deprecated as on every account bad. Let your drawings be directed to giving as exact a representation as possible of what is to be built. First, then, let no drawing be turned out without a scale, unless it be a detail to a very large scale indeed. It is quite right to write the words, "eighth scale," "quarter scale," or if you wish to be precise, "scale of an eighth (or a quarter) of an inch to one foot." But draw it also. A drawing without a scale is a lock without a key. The convenient scales to use are those found on the two-foot rules in ordinary use, and are based on a division of the foot—our usual standard—into inches and eighths of inches. The smallest scale in general use is a fortieth of an inch to the foot, otherwise described as forty feet to the inch. This is the scale usually selected for block plans to show frontage, drainage, roadways, and the like. The next in practical use is sixteen feet to an inch, chiefly employed for first sketches of buildings, and for general plans of very large complex buildings. It is almost the smallest available scale on which the thickness of walls and the position and size of openings can be indicated with any approach to correctness. The most largely used of all scales is the next one—an eighth scale—i.e., an eighth of an inch to a foot. A great deal both of arrangement and construction can be definitely shown to this scale, and the plans of extensive buildings are almost invariably drawn to it. An eighth scale is also often used for small buildings. The next scale—a quarter scale (or a quarter of an inch to a foot)—disputes with an eighth scale the honour of being the most serviceable. There can be no doubt that many minutiae, which are only with difficulty either drawn or seen on an eighth scale drawing, can be clearly shown to a quarter scale, and that consequently this is an excellent scale to build from. But anything like a large building drawn to quarter-scale covers a great deal of paper, so that the plans are unwieldy and inconvenient. Quarter-scale is, there-

fore, the scale to adopt for moderate-sized buildings, or for important parts of large ones. Half-inch scale is an admirable scale for working drawings of portions of buildings. Nearly every detail of construction can be shown to this scale, and a great many points of architectural treatment and ornament can be settled on a  $\frac{1}{2}$  in. drawing; though it must not be overlooked that most of these things, whether they relate to construction or treatment, must have been to some extent dealt with before in earlier drawings to a smaller scale. The two scales next in rotation and in use for detail drawings larger than  $\frac{1}{2}$  in. are  $\frac{3}{4}$  in. and 1 in. The latter is not infrequently employed, the former only seldom; but they are both inferior in serviceableness to the scale of  $1\frac{1}{2}$  in. to the foot, or an eighth of full size. If there are parts of the work which cannot be properly shown to  $\frac{1}{2}$  in. scale, it is generally best to draw them to this scale, which is bold and allows almost everything that has to be shown to appear clearly. It is chiefly for details of joinery that drawings to so large a scale are required. After this should come full-size details. The joiner, of course, as all of you know, makes these for every important piece of joinery on the flat slips of wood planed up for the purpose. The architect usually supplies the profiles of mouldings, and sometimes the enrichments and ornaments to full size, and in doing this guides himself largely by the effect of his previously executed working drawings to scale, and especially by the  $1\frac{1}{2}$  in. scale drawings, or 1 in. scale drawings, if such have been made. Joiners' full-size details on rods having been mentioned: I should like just to hint in a modest way that I think they are often a little more crowded up and complicated than they need be. I am aware that they ought to be compact, and I am aware also that the work of different men differs in its clearness; but I think I am correct in saying that this work as customarily carried out is often needlessly compressed together, and as a consequence indistinct, not easy to understand, and of course, therefore, easy to mistake. There are scales to avoid. For buildings, it is undesirable to employ a tenth, a fifth, a sixth, three-sixteenths, or three-eighths of an inch, and chiefly because they are not scales usually to be met with on the rules in use, and are, as a fact, not familiar. There is one other scale more often employed which is open to great objection; I refer to half-full size. Nothing can be more deceptive than a half full-size drawing. The joinery, the mouldings, the enrichments which look satisfactory on such a drawing, come out clumsy and coarse in execution; and if they are to be satisfactory in execution, they must be so drawn, if drawn to this scale, as to appear too slight. A half full-size drawing is, in fact, too bold to be serviceable as a drawing to scale, and the eye is apt to suppose that what it represents is really full size and to be deceived accordingly. It may be worth while to observe in passing that for terracotta work details have to be drawn larger than full size, as everything in terracotta shrinks during the process of burning. A point on which the practice of architects and architectural draughtsmen varies a good deal is the figuring of dimensions; but I think that anyone with actual experience of building must admit that it adds very much to the usefulness of a drawing if the important dimensions are figured, so long as it be done correctly and in the way in which the workman wants it. What is required is that the dimensions needed for setting out and regulating the work should be supplied. Of course, where the plan has no dimensions, they have to be obtained by measuring, and a draughtsman is far more likely to measure accurately in the quiet of his own room than a clerk of works or foreman on the actual job with perhaps wind and rain, and certainly inconvenient office accommodation, to struggle with. The figures on the ground plan should show the length of each main wall, and the distance from the end of each wall to the centre of the nearest opening, and from that to the centre of the next, and so on; or, if more convenient, to the centres of the piers. Always work from centres in preference to giving the dimensions up to the jambs of an opening, and then its width. The thicknesses of the walls should be carefully figured, and so should the main dimensions—in the rough brickwork—of the rooms. Do not forget that the thickness of plastering or panelling has to be deducted from these before the finished size of the room is arrived at. The heights above the ground-floor level (and below it) to the

finished surface of each floor should be figured, also the height of that level above some fixed bench mark, and it is very desirable also to figure the height of the window-sills of each story above the floor level. Where an upper floor is differently divided from the lower floor it is also well to figure the altered dimensions of the rooms. What has been said of figured dimensions might perhaps have formed part of a more general maxim—namely, that the best drawing is the one which gives the most information. Though this seems a self-evident statement, I believe it to be very unpalatable to many people whose business it is to make drawings for buildings, for not a few of them seem to consider it quite right, if there is a difficulty, to avoid it in place of attacking it. Of course, when an ignorant person makes a drawing he cannot make it so as to afford much information, because he cannot put on to the paper knowledge that he has not got in his head; but I am presuming that the draughtsman either does know or could find out, and I say that the best draughtsman is the man who encounters and solves as many as possible of the difficulties that a proposed building is likely to present, and the best drawing is the one which gives most information, especially on the difficult points. Perhaps this applies more pointedly to the preparation of sections than anything else. It is often possible for the Idle Apprentice to select such a part of the building to cut through with his section line, that nothing but commonplace construction will be encountered, so that he produces a section indeed, but one which tells the workmen little or nothing that they could not have known quite as well without it. Had it been the Industrious Apprentice, he would have chosen those parts of the design to illustrate where there really was a good deal of elucidation required, and would have produced a drawing that would have been a serviceable guide in many of the difficulties and uncertainties that are sure to present themselves as a building proceeds. There is no better way of filling one's head with knowledge about buildings than drawing them, or parts of them, from the actual object. I dare say you are all aware that a part, and probably the most important part, of every architect's training for the practice of his profession is sketching and measuring and drawing out existing buildings. Everyone who has anything to do with building—either arrangement of buildings, construction of buildings, decoration, or design—should accustom himself to this practice. You look far more keenly at a thing when you are trying to draw it than at any other time; you study it more thoroughly; you understand it better; you know what it looks like on paper, and if at any time you want to do something like it, you have the sketch to recall it to your memory, and the fact that you made that sketch will help you to draw something like it, or, at any rate, in the same spirit. These remarks apply quite as much to construction as to design or ornament. The use of the pencil is the best means of learning how to construct, as well as of acquiring a knowledge of design. Let me, therefore, urge all of you who have the opportunity of going into buildings to draw every bit of construction that comes under your notice, and not to refrain because the thing seems simple and familiar. Ten to one you will find, while making your sketch and explanatory notes, that you turn up something which you did not know before, and which you could not have fixed definitely had you been called on to draw out or describe that particular construction. Take a case in point. The skirting of a room of good quality is familiar to most of you, and you might find no difficulty in making a detail of it if it were wanted. But suppose you sketch it in a good house, you may find it grooved to the floor—that is to say, the floor boards grooved to take it. There are more ways than one in which this could be done; but one is better than the others, and if you attempted to draw it you would probably find out which is the best, and why. It is of importance not only in work which is being done for your own improvement, but in taking plans and elevations of buildings about to be altered, that you should get the habit of drawing to scale on the spot. It is not difficult to acquire. It is extremely serviceable in making your sketches and drawings good ones, and, most important of all, it generally leads to your finding out if a dimension has been read wrongly—a mistake that cannot always be avoided, especially if you are using rods.

There is not much to be said about drawing instruments. You do not require many, but they should be good. The best are of English make, next to them are the better Swiss instruments; common Swiss ones and common English ones are both disappointing. Good second-hand instruments are more useful than new ones of second-rate quality. Those which turn into more things than one, as is the case with most sorts of pocket dividers, are attractive; but they are very rarely so steady, so durable, or fitted with such good pens as the ordinary instruments, where each one is only adapted to its own functions. For any ordinary work the refinements of needle points or spring bows, or double joints, are much more trouble than they are good. It is important that all drawings which have to stand wear and tear should be in ink, and this applies especially to all drawings signed as part of the contract. Detail drawings, which will not be long in use, may very well be on cartridge or lining paper, and, though it is desirable to put them into ink, it is not so essential; but general details, such as will be in use right through a building, such, for example, as half-inch scale details, should be on stout paper and in ink. It is desirable to use a firm, bold, strong line, clear, but not too fine, and the ends of lines, joinings, mitres, and so forth should all be truly and accurately put in. A rational system of colouring is very desirable, and the general principle upon which to arrange it is to adopt colours near to those of the material represented. To colour stonework blue, for example, as is often done, seems to me a great mistake. A complete scheme of colour will be found in Mr. Phéné Spiers' book on Architectural Drawing, of which a copy will be found in the library of the Carpenters' Company. This book, I may as well say, is well worth the attention of those who wish to make themselves good architectural draughtsmen, and that as much for its excellently-selected illustrations as for its sensible letterpress. The multiplication of correct copies of drawings is a subject of some importance in plans where several copies are wanted. Probably for a single copy, tracing is the best, and though the work of making tracings is not liked, it is a very good initiation into draughtsmanship for the tracer. Tracing cloth is better to use than tracing paper, as being more durable. Mounted tracings are unsafe, as they are often distorted in the mounting. When several copies are required, a plan now in use is to reproduce them by the aid of photography. The ferro-prussiate process—a photographic one—gives copies in which the lines are white on a dark-blue ground. In another method they are dark on the ordinary white ground; but the saving of time is so great that these processes are largely made use of where many copies of plans are wanted, as, for example, by the School Board for London. I am bound to add that sometimes the drawings so made, and which I have known to be issued to builders, are difficult to decipher, and not clear enough to build from without considerable trouble and consequent risk of mistakes. The clearest duplicates are obtained by lithography, either photo-lithography or the old-fashioned but excellent line lithography. Another plan, very serviceable, and not expensive, but not, I think, so applicable to very fine work as to drawings of a bold quality of which several copies are required, is to make the drawing in anastatic ink, on properly-prepared paper, and getting the lithographer who supplies the materials to print the copies. This is, in fact, one sort of lithography. It should not be forgotten that all these duplicates give the lines only, and each must be coloured by hand if colour is wanted. There may be some who aspire to become very good architectural draughtsmen among my hearers to-night. The first requisite for anyone who sets this aim before him, is general skill in drawing. You can never carry the art of the geometrical draughtsman to perfection without some fair amount of familiarity with other sorts of art. The best training is drawing the figure from the flat, the antique, and the life, and the man who has mastered that accomplishment to some extent, will find his reward in increased steadiness of hand, sureness of eye, and power generally. Then, to be a thoroughly good draughtsman, a man must have complete mastery of his instruments, must work with as much ease with the T-square, set-square, and bow pencil as if he had only a brush or a lead pencil in his hand, and must be able almost to forget that he is using instruments. He must

also master descriptive geometry, and be ready to use geometrical methods in laying down his plans and setting up his elevations and sections, and especially in fixing the proportions of his designs. Few things are, I think, of more importance to a draughtsman, who takes up the more advanced part of architectural drawing, than drawing from memory. To be sufficiently well acquainted with a feature, or all the features of a building, to be able to draw them fairly correct, without any memorandum before you, is to have your mind to some extent stored with architectural precedents, and trained to reproduce them when wanted. All students of schools of art who are examined for certificates in elementary architecture, are now required to be prepared to draw any of the orders, Greek or Roman, from memory, and very well as a rule many of them do it; but in addition they have opportunities of showing if they can recall buildings or features in buildings sufficiently well to draw them, and I must say that, though it is only a portion of the students who attempt this, there are always some who not only attempt, but succeed well in what I regard as an excellent exercise, and one which I strongly recommend you to practise in your leisure hours. This is hardly the time to speak of the difficult art of designing architecture, but this much may be safely asserted, that the man who hopes to become a successful architectural designer, must be a facile, and should be a finished, draughtsman of architecture; limiting ourselves, however, only to drawing, it is, I think, only needful to point to a few good drawings of good work, such as occurs from time to time in an architect's practice, in order to show what skill is required of the man who has to make them. Nowhere can you see a better selected set of examples of this than in Mr. Spiers' book, though were this lecture a conversation with a few of you in a room where it would be practicable to refer to small-scale drawings such as would be lost on these walls, the case could be made even stronger. I may, however, refer you to illustrations copied or photographed from architectural drawings which appear from time to time in our professional journals as examples of work requiring the greatest skill. In the matter of highly-finished drawings, English draughtsmen yield to none as far as line work is concerned; but when we turn to what are called washed drawings, that is to say, drawings shaded in sepia or Indian ink, and coloured drawings, we must admit that though these things are fairly well done sometimes in England, especially by men who have studied abroad, French draughtsmen, as a rule, are far more skilled in the method, employ it more often, and carry it to a higher degree of finish. The drawings prepared by architectural students who have gained the Grand Roman Prize, and go as travelling students to Rome, are, as a rule, wonderful specimens of draughtsmanship.

We will now turn to perspective drawing or pictorial drawing, the sort of drawing which has for its aim to represent solid objects as they appear. As I before said, geometric drawing produces diagrams to scale, each one giving only one face, one aspect, of a solid object. Perspective drawing is not to scale, and produces drawings which are pictures and not diagrams, and which attempt to show solid objects as the eye sees them. It is quite true that as applied to buildings perspective drawing is chiefly used to show what an intended building will look like when it is built, and we are not much concerned to-night with other applications of the art; but please understand that the laws of perspective affect every solid thing, and that landscapes, portraits, still life—in short, everything that a painter depicts, must be correct in perspective if it is to be a true representation, and that the study and practice of perspective are matters of a much more extended application than to the representation of buildings only. Suppose you go to a small railway station at some place where a straight run of line extends for miles, and you wait for a train. At first you see a mere speck far off, which it is difficult to make out. While you look the speck becomes more distinct. As it nears us it seems to grow and grow, and as you fix your eyes on the train during the last hundred yards or so it seems literally to swell, so rapidly does its apparent size increase, till it comes to rest at the platform. As it moves off the great bulk begins to shrink, at first rapidly, and then more slowly, till it once more has diminished to a mere speck. If we glance at the rails on which it has

draw a house, rectangular on plan, standing in such a position that you see both its front and flank, or if you get a good photograph of it and then prolong all the lines representing things that are level, you will find that they form two groups or series which actually do meet, and meet at two points on the horizon far apart, one to our right and one to our left. These, in perspective, are termed vanishing points, and in representing objects in perspective we must make use of such points and draw the lines tending towards them. We naturally, therefore, inquire where they will be found. We already know that they are on the horizon, and if you look towards the horizon in a direction exactly parallel with the direction with one of the two series of lines, say that series which consists of lines on the front of the building, you are looking to the vanishing point of these lines. If you now turn through a quarter-circle and look to the horizon once more, you will be looking in a direction parallel to the end of the building, and also looking to the vanishing point of the other set—namely, those lines which lie at right-angles to the front—those which are on the flank of the building. This is the case whether you are sketching an existing building in perspective or making out the outline in perspective of some intended building. When your objects are rectangular, as is the case with 19 buildings out of 20, your vanishing points are always 90°—a quarter circle—apart; and it may be easily understood that it is not always practicable to place both of them, or even one of them, on even a very large sheet of paper. There are various contrivances for drawing the lines of a perspective drawing towards a point away from the drawing (the best of them is the instrument called the *centrolinead*); but it is always simplest and best, if possible, to work at a large drawing-table; pin down the paper securely, and draw the lines towards the actual points (marked on it with pins) by the help of two long straight-edges. When the drawing represents an interior it is frequently, in fact usually, the case that only one vanishing point is required, and that point is on the paper and in the picture. In most good interior perspectives you will note that the lines are all drawn converging towards a point in front of the spectator. It is often usual to call this a point of sight; but it would be better not to invent a new name, as it differs in no respect from a vanishing point such as we have talked about. Suppose you were to take a picture-frame, the size of an intended picture, and put a glass in it, and fix the frame, and also fix at your station a card with a small aperture to look through, you might, if you had a kind of ink that would make lines on the glass, trace the outline of your objects on it, and of course a straight line—say a wire—stretched tight from the position of your eye to any point in the building would pass through, if it could penetrate the glass, just at the spot where that point in the building from which it starts is represented on that outline. The process pursued in making a drawing from plans and elevations of an intended building is a little like a representation on paper of what you would see if such a series of lines as I have suggested could exist. You make a plan of the building, or of so much of it as would be visible from the point where the spectator would be put. You mark by a line on the plan position of the picture, which it is convenient should touch the plan of the building at one or more points. You then draw a series of lines from all the corners, centres, openings, and other features of the building to the station of the proposed spectator, and where they cut the picture line on plan will give their position in relation to one another in the picture. You find the vanishing points by drawing two lines on the plan, starting from the position of the spectator and parallel to the front and side of the object, and continuing them till they cut the picture line. The heights are obtained by a little management, the basis of the mode of dealing with them being that every upright line, which on the plan would touch the picture, is to be drawn the full height of its geometrical representation, and all others shorter than that, as they are near to, or further from, the picture. The information you now possess, if I have made it clear to you, is almost all that is required for ordinary work by the perspective draughtsman; but then he must add to it a great deal of skill, and no small amount of practice. Perspective drawing may be made one of the most difficult and perplexing subjects, and it figures as such a subject in most books. I

come and gone, and which we know are laid accurately parallel, they seem to be converging towards a distant point, and each sleeper appears shorter than the one this side of it, and each interspace from sleeper to sleeper seems smaller as they get further off. We recognise thus that objects diminish in apparent size as they get further and further off. If this is so, that quoin of that part of some small station building across the line which is furthest from us must appear less in height than the quoin nearest us, and we recognise that it is so. The horizontal lines of the top and bottom of the station wall appear to be sloping—the top line sloping down, the bottom line sloping up. Of several windows all of the same size, each one looks smaller than its nearer neighbour, and larger than the more remote neighbour. Each telegraph pole seems to be growing shorter as the line recedes, and, like the eaves of the station roof, the telegraph wires also seem to slope. If we see the end as well as the side of the station building, the horizontal lines of that part of it appear also to slope, but in a different direction from that towards which the lines of the side slope. If all this is correctly drawn for us we recognise that it properly reproduces the appearance of the actual objects; and if a set of correct geometrical plans and elevations of the station, &c., are before us at the same time, we recognise how completely different the one thing is from the other, and we ask ourselves, On what does it all depend? What is the principle involved? Are there rules to guide us in imitating on paper these appearances? The principle involved in the perspective of solid objects is that light travels in straight lines. You may consider that the rays of light from the sun falling on the objects which he lights up are reflected from them in every direction in straight paths, and it is just those whose path lies straight from the object to our eye which enter the eye and paint a picture, so to speak, on the back of it. The path of light from any given point to the spectator's eye is a straight line. The wider the angle at which the two rays starting from opposite ends of an object enter the eye, the larger the image on the eye will be, and the larger will this object seem to be; the more acute the angle, the less space does the image of the object take in the eye, and the smaller will the object appear. Let us take our station building as an example. Suppose a pair of lines drawn from the near end of it through space to the eye of the spectator, and suppose another pair of lines, drawn from the further end to that eye. The apex of the triangle which the first pair of lines make, with the corner of the building as its base, is much more blunt than

that which the second pair of lines makes, consequently the two rays of light enter the eye from the nearer corner, at a much wider angle than those from the further corner, and the nearer corner accordingly takes up more of the field of vision and seems bigger. The same reasoning would apply to any other pairs of points on the building that might have been selected, and to the paths of light joining them and the spectator's eye; and as one result if the vertical line which is distant appears shorter than the one which is near the lines joining them, which represent the top and bottom of the wall, must appear to converge towards each other. We noticed, in fact, just now that in looking at a building its top lines appeared to slope down, and its bottom lines to slope up. At some point between the two, therefore, we should expect that a level line might occur on the building which would neither appear to slope up or down. This is so; such a line would have to be exactly level with the spectators' eye, and we call it the horizontal line; everything that you look at all down upon appears to be tending upwards towards the horizon—everything you look at all up to appears to be tending downwards. In nature the most remarkable display of the horizon is at the sea-side, where the apparent edge of the sea is the horizon. By changing your position, so as to be higher or lower, you alter the horizon line. Thus, if at our original little building you were to get a ladder, and go up it till your eye was on a level with the eaves of the roof, you would find that the eaves-line had become the horizon line, and appeared level, neither sloping up nor down, while the base of the building seemed to slope upwards much more than before. On the other hand, if you get down from the railway platform, on which we may suppose you to have been standing, on to the line itself, and stoop till your eye is level with the platform—i.e., level with what the station stands on, you will see that the base of the building now appears level, as it coincides with your horizon line for the time being, and the eaves line will now appear to slope down at a more rapid rate than before. If you watch our building once more, you will not be long in detecting that each of the sloping lines representing horizontal ones slopes more rapidly according to its distance from the horizon, and you will soon decide that all the horizontal lines on its front appear to be pointing towards one point, and that point somewhere on the horizon, and that all such lines on its flank seem to be pointing towards another point also on the horizon. If you accurately

strongly advise those who wish to learn it to get personal instruction, and that over a drawing board. You may probably find instruction in a class, where the teacher is practical, which will answer the purpose; but the best method is, after a very little study of the principles, to begin a drawing under the guidance of someone who is familiar with this sort of work. You will find it quite as difficult to learn perspective drawing by a book alone as to learn in the same manner to ride on horseback, or to play at cricket. It was stated early in the lecture that perspective has to do with other things beside buildings with straight walls and roofs. See a line of soldiers, straight, well set up, and perfectly in line. They look like a wall, and if you drew them you would draw them like a wall. Let the word be given to fall out, and the wall dissolves; but the men of whom it is composed, though they have dissolved into irregular groups, are just as much influenced by the laws of perspective as before, and their apparent size is just as much diminished if they are at the remote part of the parade ground as it was when they were at the remote end of a formal line. In drawing or painting the human figure, and in other artistic work, what is called foreshortening, which is one of the sources of artistic effect, is very much practised. This is perspective. Represent a man with his arm stretched out across the picture like a sign-post, and you have a bold figure not very difficult to draw; but let him swing his arm round and point right at the spectator, or nearly at him, and you tax the resources of the most skilful draughtsman to render correctly on paper the effect which this attitude produces on the spectator. Foreshortening, or in other words the perspective of the human figure, needs much practice to manage it well. Another use of the word perspective is to be found in the mouths of those who discuss paintings, especially landscapes. I refer to aerial perspective, for which phrase might be substituted "effects of atmosphere." Here is no longer any question of outline, but of those sobering effects due to the distance of an object, which rob its outlines of sharpness, its colouring of contrast, which hide much of its detail, and harmonise and blend together things that would be distinct and separate were the object nearer to the spectator. This is not, properly speaking, an effect of perspective at all, but it is an effect of distance, and it seems to have acquired a name which gives it some claim to mention when perspective is being considered. In taking leave of the subject, I wish to come back from any reference to the painter, or even the perspective draughtsman, to the sort of drawing which is more immediately the concern of most of us. I strongly recommend any who do not draw to make an attempt to learn. It is like acquiring a new language. After you have been practising drawing for a time, every drawing that comes into your hands has a new meaning for you, just as when you have done exercises in a foreign language for a time you begin to find that books in that language cease to be impenetrable mysteries to you, and find a voice with which to address you. When you get further, and are able to make good, useful drawings of intended works, you begin to feel like the man who has mastered a foreign tongue sufficiently to be able to speak in it; and it is not alone the sense of a new power which is desirable, valuable though that may be, but that power makes you a more useful man, and a more valuable man on a building, in whatever capacity you may be engaged, and will give you more certainty of employment and better prospects of good pay. Only let me urge on those who learn to draw to fix it in their minds that they must draw *well*. Your work, whether simple or otherwise, should be clear, vigorous, distinct, free from blunders, executed with a clean line, true to scale, and, in short, good in quality.

The Rev. W. Haworth, acting as surrogate to Lord Grimthorpe, presided over a Consistory Court, held at York Minster on Thursday, the 6th inst., when a faculty was granted the vicar and churchwardens of the parish church of Selby, to take down the modern roof over the two western bays of the south aisle; to fix a new roof to correspond with the ancient portion of the roof; to take down and re-fix an organ; and to make certain other alterations.

At Friday's meeting of the town council of Arbroath, N.B., it was decided to purchase the Abbey Lodge at a cost of £1,050, in order to maintain the amenity of the Abbey ruins.

#### WAYSIDE NOTES.

I NOTED no foreshadowing of a great benefit to the architectural profession in the Queen's Speech. An item of some interest, however, is the promised reintroduction of a Bill to facilitate and cheapen the transfer of land in England, which, as I have at times pointed out, should be a measure calculated to encourage gentlemen to build their own houses rather than to buy or rent houses erected by strangers. Then it is interesting to know that, having got a new Employers' Liability Act, means are to be taken to pass a Bill for ascertaining the liability of employers in cases of accidents, which would be better business for the employers than the employed. It is well, too, that measures are to be taken with a view of consolidating and amending the laws relating to the public health in the Metropolis. Something in this way has long been required. I am glad, above all, that Her Majesty should state that attention is to be drawn to a very urgent matter, and that is the insanitary condition of many of our camps and barracks, the latter of which too often of late have proved to be little else than hot-beds of malignant fevers.

Judging by what has come under my notice through the Press and private sources of information, the Dublin barracks are worse than any. I am told the whole of the existing arrangements there ought to be swept away, and new buildings erected for the accommodation of the troops. It is, I believe, a fact that the drainage system has been many times the subject of extensive repairs, &c.; but that, as might have been expected, no patching up of an old drain-system is of any permanent benefit. Doubtless there are very many other of our soldiers' homes that require most drastic alternative measures to render them really fit for occupation. With camps, as distinct from barracks, there should not be difficulty in rendering them thoroughly healthful, since they are generally composed of a number of small, low buildings, with light and air all round. But there is no excuse for the unwholesome conditions under which our soldiers are placed in many barracks. The buildings could be made as healthful as possible if more energetic measures were taken by the authorities.

The fact is, I believe, the existing drainage arrangements to be found in all but the most recently-erected barracks are altogether behind the times. Since these were planned, sanitary science has made great strides, and methods which a few years back may have been considered as good as could be are now condemned. I am assured that in many barracks the whole of the sanitary arrangements require to be thoroughly overhauled, and that means thorough reconstruction on scientific principles, which scientific principles moreover require to be in harmony with the manners and customs of Tommy Atkins. It is ridiculous to say that modern arrangements cannot be employed because carelessness and misuse will put them out of order. The arrangements should be so designed that it would be impossible to put them out of order. A modern drain-designer conversant with every improvement in systems and detail, knows that there is now no possible excuse for not rendering the drainage of any ordinarily-shaped building perfect in principle, safe against misuse, and capable of easy and rapid sweeping and cleansing in any and every part, be it pipe, trap, closet, or waste. I feel very strongly about this question of the sanitary conditions of barracks, and trust that the attention to be directed to the matter during this Session of Parliament, may lead to great alterations and a vast improvement in the sanitary condition of the buildings in which our gallant soldiers are housed.

A "Sanitary Registration" Bill is included in the list of private Bills to be introduced early this session. If drafted on a modified form to that of the first Bills brought into Parliament on this subject, the measure may prove useful. If merely brought forward by a syndicate, for commercial ends, it is best thrown out.

Now that Parliament has reassembled, let us beat the big gong and sound again the war-cry of Registration. I do not see any mention of a Registration Bill for Architects in the lists given; but I understood last year that steps were to be taken to bring it before Parliament at an early date in this session. I hope that all things are decently in order to this end, the Bill perfected as far as possible, additional

petitions signed, adversaries overcome, and other advances made. There is nothing like being early in the field where Parliamentary Bills are concerned, and no delay should be allowed to take place before the drafted measure is put in a skilful pilot's hands to steer through the always difficult course in the sea of Parliamentary criticism. The way of an agitation for the compulsory registration of architects is now well prepared, and happenings of the past few years must have put the public in a temper to believe that the architectural profession wants some sort of reorganisation. And as this reorganisation means ultimately increased education, as Mr. Robert Walker would have it, which is only to be attained through a system of compulsory examination and Registration, it would surely not be difficult for an able advocate to demonstrate in Parliament the need for the reform contemplated by the Architects' Registration Bill. Anyhow, I look forward to seeing the Registration Committee once more energetically astir, and renewing their striving for that which, in howsoever many years, must at last be attained in its completeness.

Touching the Blackwall Tunnel scheme, Mr. William Saunders, writing to the daily papers, proposes to substitute lifts for the inclined approaches to the subways. I hardly think the suggestion practical. Assuming that the tunnel is to be constructed, it will, it is hoped, be of such utility to so large a mass of trading citizens and others that continuous streams of waggons and vehicles would be passing along either subway. In which case, it is evident that no amount of provision in the way of lifts would suffice to keep the way clear of congestion. Neither would the various waggons, &c., descending, nor those ascending, be in sufficient quantities to make the utmost use of the tunnel. If the traffic through is to be always thin and desultory, it will be as well not to think any more about the construction of the tunnel, as it would be scarcely wise to expend from one and a half to two millions sterling on a work to benefit only a few East-end tradesmen. The County Council have been advised by their Bridges Committee to proceed with the scheme as planned by Sir Joseph Bazalgette; but they would surely be only showing ordinary caution if they first took pains to ascertain the amount of benefit to be conferred on the community at large by the construction of the tunnel before committing themselves to an enormous expenditure that must materially affect the rates. Having ascertained, beyond a shadow of a doubt, that the tunnel *will* be a public blessing, let them proceed to its construction as originally designed, avoiding the giving ear to suggestions about lifts and elevators.

I hope that some kind friend will let you have the plates of the beautiful Norfolk screens, to which "Decorative Painter" referred last week. Doubtless, by this, you have had many offers, and Mr. "D. P." and others of us interested in Norfolk ecclesiastical work, will have the pleasure of seeing them reproduced when you have time and space.

Of Egyptology, as a science, I know little or nothing. I am deeply interested, however, in all things pertaining to ancient Egypt, its people, their manners and customs, and architecture. Nevertheless, it completely passes my comprehension to understand where they got twenty tons of mummified pussy-cats from! I can believe that if an army of ancient Egyptian embalmers were left to roam about the tiles of London they might in a short time prepare an astonishing number of feline mummies; but where and how the Liverpoolian salesman obtained his twenty tons I cannot divine. Anyhow, they sold well. It would scarcely have pleased the owners of the sacred cats to have known they were only having the animals embalmed to be, some thousands of years after, sold as manure in a country whose civilisation would rise on the ashes of that of classical nations. The moderns have little respect for antiquity, either as represented in mummy cats or other ways. I understand that classical Tivoli is to be the site of an electric-lighting station for new Rome. Imagine the echoes of Tivoli, of all places, becoming awake with the whirring of dynamos. Tivoli, where exist the ruins of the charming little circular temple, whose beautiful "order" should show us that the ancient architects were not such machine-like designers as we are prone to think. GOTH.

CONTEMPORARY BRITISH ARCHITECTS.

SEE description on page 256.

WHALLEY CHURCH, LANCASHIRE.

We give herewith two views of this church, contributed by Mr. John Langham, whose drawings and plan of Whalley Abbey and Gate-way appeared in our pages for July 5, 1889. Some account of these buildings was then given, to which reference may now be made. Whalley Church has a special interest other than that of strictly architectural merit, seeing that it is said to have furnished the scene of some of the leading incidents depicted in Harrison Ainsworth's "Lancashire Witches." The chancel dates from 1220, and there are some canopied stalls in the interior of the church brought from the abbey. Three Runic crosses stand in the churchyard.

"THE ARCADIAN SHEPHERD."

The most noticeable group in last year's Royal Academy Exhibition in the galleries devoted to sculpture was Mr. W. B. Richmond's noble figure of which we give an illustration to-day—viz., "The Arcadian Shepherd." Owing to the fact that the artist failed to obtain a photograph of the work before it was shown at Burlington House, and in consequence also of the refusal of the Academy authorities to allow a photograph to be taken while it was on view, no good illustration of this masterful statue has hitherto been published. Mr. Richmond had special views of the group taken for us by Mr. Fred. Hollyer, and thus we are enabled to present our readers with the illustration of it to-day. Milton's lines, quoted by the sculptor in allusion to his work, are printed on the lithographic sheet.

UPSALA CATHEDRAL, NORTH TRANSEPT PORTAL.

THE University city of Upsala is but a comparatively modern successor to an ancient town near by, the history of whose foundation is lost in the myths of antiquity. It is said that somewhere about the year 10 of our era, Fryer, the descendant of Odin, made it the capital of his Kingdom of Upland, instead of the more ancient Sigtuna, and built in it his palace and a temple to the gods. Gamla (old) Upsala is situated about three miles from Upsala in the middle of a flat country broken only by a large number of tumuli, the three largest of which are popularly supposed to contain the ashes of Thor, Odin, and Fryer. Some of them have been opened and proved to have been burial places, but nothing of value was discovered. Behind these larger tumuli stands a curious building which was once the Cathedral of Upsala, and may have been in part the temple of Odin. It consists at the present time of a fifty square tower forming a nave, with an long chancel beyond of the same width, ending with an apse. Before the tower, but not central

to it, is a large porch. The chancel and porch appear to be entirely of Early Pointed work, and are built of granite with brick arches. It is quite impossible to fix the date of the tower. It is square, built with rough granite rubble facings in large blocks, and has on each of its four faces two lofty round-arched doors, with large rough voussoirs. These doors must have been open to the air on all sides before the erection of the chancel and porch, and this fact, to a certain extent, supports the theory that the building was not at first intended to be a Christian church. In plans published by Peringskiöld in 1710, remains of transepts are shown, and these, together with the shell of the church, may have been constructed by the first bishop, an Englishman, about 1026. The tower at present is finished with gables on the east and west faces, but there are indications that there was a gable on each face, and that the tower has been heightened. Within the churchyard inclosure to the north of the church stands one of those singular wooden towers, more common in Norway than in Sweden. There is nothing about it to determine its date, but we know that it was standing here in the 17th century. It is raised on a platform of rough granite, and has its roofs and supporting struts covered with oak shingles. It appears to have been usual in Upland, when the churches had no towers, to build detached wooden belfries, and the neighbouring church of Waksfala has a similar one, open all round, and showing the bells. Towards the end of the 12th century Upsala was created an archbishopric, and the increased importance thus given to the city seems to have suggested its removal to a more convenient situation; and about 1273, Archbishop Falke made arrangements for the transfer of his seat. Much as in the case of Old Sarum, which had been similarly left for a more convenient site fifty years before, the Archbishop selected a position on the banks of a river, the Sala, where it commenced to be navigable, and on the rising land near by laid out the ground for his new cathedral. There was already a small town in existence on the site known as Ostra-Aros, and the Church of the Trinity now standing to the south of the cathedral may have been built before the date of the transfer. The first thing the Archbishop had to do was to discover an architect—no easy task, as, at least in Mediæval times, Scandinavia was never able to produce one; and it is a curious fact that the three cathedral churches of Scandinavia were not only designed by foreigners, but by men from different countries; and in all essential features Upsala Cathedral is French, Lund is German, and Thronhjelm is English. The fame of the magnitude and beauty of the buildings rising everywhere in France at this period had reached the Archbishop through the Swedish students then studying in Paris, and he applied to the Provost of that city to select for him an architect to design his new cathedral. The Swedish students themselves raised forty silver livres to defray the travelling expenses; and an architect engaged on the works at Notre Dame was accordingly selected. His letter of appointment is still extant, and it partly runs thus:—"Estienne de Bonnuell, tailleur de pierre Maître de faire leglise de Vpsal en Suece, proposant a aler en la dite terre, si comme il disoit, et reconnut endroit qui pour mener et conduire au couz de la dite Eglise, aueques lui tex Compaignons et tex Bachelers." "En tesmoing de ce, nous avons mis en ce lettres le seel de la Preuost de Paris, lan de grace Mil. CC. quatre vinz et sept, le Semne di devant feste S. Gile et S. Leu et nous le tampscriit de ces lettres auon seelle du seel de la Prevoste de Paris. Ce fu fe lan et le jour defus dit." Thus the date of his engagement is accurately fixed at 1287. He is described in his letters of recommendation as the architect of Notre Dame, and the date of his appointment coincides with a lull in the progress of the works at that building, and it will be interesting to note the state of Notre Dame as he left it, and to see how far he followed it in planning his new cathedral. What his age was we do not know; but he may have remembered the great fire which about 1240 so much damaged the building, and he may have served his apprenticeship on the repairs begun about 1245, when the chapels between the buttresses of the nave were built. In any case, he would probably have been engaged on the alterations of the transepts begun in 1257, when also the first three chapels eastward therefrom were built between the buttresses of the choir, unless, indeed, he were with de Cormont

at Amiens at that time, of which there is some suggestion. When he left for Sweden, the old arrangement of the apse at Notre Dame remained unaltered; but before he left he would know of the intention to remodel the east end—at all events, it was on Amiens rather than Paris that he based the design for the Upsala apse. On plan, Upsala Cathedral consists of a nave of six bays, with aisles and chapels between the buttresses, aisleless transepts projecting but slightly beyond the chapels, a choir of five bays, with aisles and chapels terminating with a semi-octagonal apse, with its surrounding aisle and chapels. Up to the apse, except in the number of the bays and aisles, the plan is identical with Notre Dame, and the arrangement of the apse is equally like Amiens, except that the radiating chapels are reduced to five in number, but the central one is prolonged by a bay as there and at Rheims. At the west end are two towers and there was a flèche at the crossing; and to the west front and the two transepts are deeply recessed portals. The whole of the plan, with the possible exception of the south transept, where there are heavy diagonal buttresses carrying turrets, would seem to have been Estienne de Bonnuell's, and the north portal, which is of stone, must have been erected by him, as the mouldings and the tracery are of the character of French work of his date. The west front has only one portal, and over it and over that of the north transept, is a large traceried rose window. The illustrations we give of the north transept portal will best convey an idea of Bonnuell's work. The figure in the centre is St. Eric, one of the saints to whom the cathedral was dedicated. With the exception of the portals, some of the tracery of the windows and the main piers of the building, the whole structure is in brick, and all the upper parts of the nave transepts and towers were completed with flat-brick arcading and ornaments, in the manner common all round the Baltic, by an architect other than Bonnuell. The picturesque and fantastic spires and flèche, shown in a plate by Schröder, were erected in Gustav Adolf's time by De Besche, a Protestant refugee from Liege. These were destroyed, and the cathedral much damaged by a fire in 1702, when the hideous roofs and towers, till recently standing, were erected. The sacristy contains an interesting and valuable collection of Mediæval jewelled plate, sceptres, and crowns, which may account for the great doors being all sheathed with iron plates, riveted on like plate armour. In the principal chapel behind the high altar is a magnificent tomb bearing the effigies of Gustavus Wasa and his two queens, with lofty obelisks at the corners, and surrounded by paintings on the walls of the principal events of his life, executed in fresco by Professor Sandberg. The structure has suffered so much from fire, neglect, and rebuildings that it would seem, short of total destruction, no worse fate could befall it; but the hand of the restorer is once more laid heavily upon it. At the present time the whole of the building, inside and out, with the exception of the choir, is under restoration, and every part so thickly covered with scaffolding as to make it impossible to see exactly what is being carried on; but on the floor of the nave large blocks of moulded concrete are being cast and finished off for the upper parts of the building as buttress-heads and pinnacles, and the skeleton framework of two lofty spires in iron is nearly completed. The designs for the restorations were prepared by the Swedish architect, H. Zetterwalls.—J. TAVENOR PERRY.

HOUSE ON THE CLAREMONT ESTATE, NEAR MANCHESTER.

THIS house is now being built on the estate of Sir Percival Heywood, Bart., at Claremont, about three miles from Manchester, a portion of which estate it is now proposed to lay out for the erection of villa residences. The walls are of local red brick, and the roof and upper portion of the walls are covered with red Brosely tiles. The builder is Mr. James Birch, of Manchester. Mr. Bertram Heywood, B.A., of Uttoxeter, is the architect.

NEW OFFICES, BOLTON.

THIS block of buildings, now near completion, are situate at the corner of Bradshawgate and Nelson-square. They are substantially built of Ruabon terracotta and red bricks, and roofed with tiles of the same clay. The whole of the basement is lined with white and brown glazed bricks. The internal fittings of the ground floor

are of American walnut; the floors, which are fireproof, are laid with cube mosaics, the walls being faced with marble mosaic adamant above the wainscot dado, which is also of walnut. The vestibule screen is in terracotta, the entrance gates being wrought iron. The ceilings are panelled in plaster and walnut mouldings. The whole of the ground floor will be occupied by the Prudential Assurance Company (Limited), and will contain large banking room, private office of the district superintendent (Mr. Councillor J. C. Stredder), and a room for the assistant superintendents, w.c., lavatory, &c. The upper floors are already let to professional men, while caretaker's rooms are provided in the roof. The general contractors are Messrs. Burrows and Son, Bolton; the terracotta and facing bricks are by Messrs. Monk and Newell, Ruabon; and the pavement lights by Messrs. Hayward Brothers and Eckstein, London; the whole of the works being from designs and details of Mr. Ralph B. Maccoll, architect, Bolton, who has superintended the works throughout.

#### ARRETON MANOR HOUSE, I.W.

**T**HE village of Arreton, or Atherton, lies under the down of the same name, about five miles east of Newport, in the Isle of Wight. Much ancient work remains about this part of the island, but so modernised as to be scarcely recognisable. An honourable exception to this is the old Manor House of Arreton, from which the present sketches were made, which remains much as it was in the 17th century. The manor at one time belonged to the Abbot of Anarr, and so came to the Crown with the rest of the plunder at the Dissolution of the Monasteries. It was bought of Charles I. by Sir Levinus Bennett, and thence came by marriage into the Fairfax family, and so to the present holders—the Wickham Martins, of Leeds Castle, in Kent. With regard to the illustrations, they may be said to speak for themselves. The details are good specimens of the work of that period.

PERCY G. STONE.

#### CONTEMPORARY BRITISH ARCHITECTS.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

**T**HIS sheet is the sixth double-page group of architects' photographs which we have given, and we are glad to learn from all quarters how thoroughly these portraits are appreciated by our readers. The following notes give a brief outline of some of the work executed by those who are herewith represented:—

Mr. W. M. Fawcett was a pupil of the late Mr. C. W. Burrell, of Leeds. After completing his term of articles, he entered the University of Cambridge, and took his degree in 1859, being classed as a senior optime in the mathematical tripos. Soon after that he commenced practice on his own account. He was elected as county surveyor in 1861, and in connection with that position he remodelled and nearly rebuilt the Cambridge County Gaol, and he built the Police Station. Additions were also made to the Militia depot and the Lunatic Asylum. In ordinary practice he has carried out a large number of houses and vicarages. East Norton Manor House, near Leicester, Longstowe Hall, near Cambridge, and the mansion at Breaghwy, near Castlebar, for the High Sheriff of co. Mayo, are a few of the more important private houses built by him. He has erected a considerable number of schools in Cambridge and the neighbouring counties, and is at present building the new school for the Governors of the Perse Trust in Cambridge. He also erected the Cavendish Museum, presented by the Duke of Devonshire to the University. He has since built the Comparative Anatomy Schools, and is now carrying out the Schools for Human Anatomy and for Physiology. Among college buildings may be mentioned his additions to King's, Queens', and Emmanuel. The principal front also of Queens' College was restored by him. The Master's Lodge at St. Katherine's and the Tutor's Lodge at Trinity Hall are also his work. The Local Examination Offices were built by him for the Syndicate which manages these examinations. The University Cricket Pavilion, the University (Goldie) Boathouse, and the boathouses for Jesus and Caius Colleges were erected by him. He has had considerable practice in church restoration: among many others may be mentioned Barton,

Boum, Cottenham, Knapwell, Longstowe, &c., in Cambridgeshire; Acton, Aldham, Little Bradley, Cockfield, Great Wrating, and Great Thurlow, in Suffolk; Seaton, in Rutland; Morley, Isham, Pedley, and Pentlow in other counties. In literary work Mr. Fawcett some years ago edited Paley's "Gothic Mouldings," and has since written an account of Mr. James Essex's journey in Flanders, which was published by the Cambridge Antiquarian Society, of which he has been treasurer for some years. He was elected F.S.A. in 1874, and F.R.I.B.A. in 1866, of the latter of which bodies he has been several times, and is at present, a member of the Council. The photograph is by Mr. Lord, of Cambridge.

Professor J. Henry Middleton, F.S.A., M.A. of both Oxford and Cambridge, D.C.L. of Univ. of Bologna, Fellow of King's Coll., Cam., is the Slade Professor of Fine Art and Director of the Fitzwilliam Museum at Cambridge. His literary works are well known for their learning and ability. They comprise "Ancient Rome in 1885," and a new edition, "Ancient Rome in 1888"; articles in the *Encyclopædia Britannica* on Painting, Sculpture, Pottery, and more than eighty other subjects; various articles in the *Archæologia*, *Archæological Journal*, *Journal of Hellenic Studies*, and other antiquarian periodicals. Among the architectural works by Professor Middleton, acting in partnership with the late J. Middleton, are the Ladies' College, Cheltenham; SS. Philip and James Churches, Cheltenham; and about a dozen other churches; a picture gallery for Mrs. Heurtley at Hampton Court; Coleshill Court for Captain Digby, and Beckford Hall for Captain Case-Walker. In partnership with Messrs. Prothero and Phillott at Cheltenham, Professor Middleton has carried out the new part of Lampeter College; Trinity Church, Aberystwith; the Red House at Oxford, and various other houses and churches chiefly in Gloucestershire and South Wales. Professor Middleton was born in 1846. The portrait given is by Messrs. Stearn, of Cambridge.

Mr. Somers Clarke and Mr. J. T. Micklethwaite were pupils of the late Sir Gilbert Scott, and have always worked together. They began to practise in 1869, and the first important work carried out by them was the rebuilding of the parish church of All Saints, West Bromwich. It was soon followed by the great church of St. Martin, Brighton, and the church of St. Hilda, Leeds, and ever since the architects have been much employed on church work, both in the erection of new buildings and the repair and adaptation of old ones. Amongst the more notable are St. John's Church, Gainsborough, with schools and other buildings, making a large group, the churches of Sharlston and Horbury Bridge, with several others in Yorkshire, one being St. John's, Wakefield, an 18th-century building, which is being enlarged and adapted to modern wants in the Italian style of the original work. Another important work now going on is the enlargement of St. Peter's, the present parish church of Brighton, which will make it a fabric of the first class. Amongst the ancient churches which the architects have put in order are those of Ardington, Berks; St. Nicholas, Brighton; Cherry Hinton, Cambridgeshire; Colwall, Hereford; Harrieston, Kent; Helpringham, Lincolnshire; Headon, Notts; Inglesham, Wilts; Ifield, Sussex; Meriden, Warwickshire; Potton, Beds; Raveningham, Norfolk; Sidbury, Devon; Thornhaugh, Northampton; and the curious church of Thorney Abbey, which, though a parish church, is the private property of the Duke of Bedford. Of works other than churches are the remodelling of the Sussex Eye Hospital and the building of the Northern Dispensary and the Western Dispensary and Hospital, all at Brighton; the decoration of the hall at Merton College, Oxford; the enlargement of the House of Mercy at Horbury, and the Convent, Woodside, Croydon; extensive alterations at Barcombe Place and Kingston House, Sussex; Thorrock, Lincolnshire; Raveningham Hall, Norfolk; and many new houses of less importance. We lately published a view of Reid's new hotel, now being built at Madeira, where also several private houses are in hand. There are also a number of houses going on at Malaga, and drawings are being prepared for an hotel there. Mr. Micklethwaite was elected a Fellow of the Society of Antiquaries in 1870, and Mr. Clarke in 1881, and each have served several times on the Council. They were amongst the twelve architects first selected by Mr. Christian for the Liverpool

Cathedral competition, and amongst the six who prepared plans for the new Church House. Mr. Micklethwaite is the author of a book on "Modern Parish Churches," and both he and Mr. Clarke have written many papers on architectural and antiquarian subjects which are printed in the *Archæologist*, the *Transactions* of various societies, and elsewhere. The portrait of Mr. Clarke was taken by Messrs. Fry, of Brighton, and of Mr. Micklethwaite by Messrs. Hall, of Wakefield.

Mr. Thomas Verity, F.R.I.B.A., now in partnership with his son, Mr. Frank T. Verity, was the architect of the Criterion restaurant and theatre erected some years ago for Messrs. Spiers and Pond. The design was chosen in competition. Previous to this Mr. Verity had been associated with the detail work of the Albert Hall, if we remember correctly, as well as other work at South Kensington. The Gaiety restaurant was converted and enlarged by Mr. Verity, incorporating part of Mr. Bassett Keeling's once famous, and much-abused Strand Music Hall front, which was said—at the time it was built—to inaugurate the "Victorian" style of architecture. The Empire, Comedy, Novelty, St. James's, Royalty, and Folly theatres were designed by Mr. Verity, and he built the Civil Service Stores in the Haymarket. Among his largest works in London are the Kensington Public Baths and Wash-houses, Albert-gate Mansions, houses in South Audley-street at the corner of Mount-street are recent works by this architect, who also designed the rich terracotta front in James-street, Westminster, for Messrs. Hill's bakery. The new saloons, grand stand, and pavilion at Lord's Cricket Ground are being executed under his supervision. The *Nouvel Hôpital Français*, carried out in Shaftesbury-avenue, is one of his works, in conjunction with Mr. G. H. Hunt. The Scarborough Spa Saloons, a vast work in which iron on a large scale is employed, is from Mr. Verity's plans, and he also designed the Nottingham Municipal Buildings, won in competition; and another work of his comprised the enlargements and additions made a few years ago to the Agricultural Hall at Islington. Mr. Verity's design, in partnership with Mr. Hunt, was placed second in the late competition for the new Admiralty and War Offices. The decorations erected in Waterloo-place on the occasion of H.M. Jubilee were designed by him, and it will be fresh in the memory of many how substantial and effective the scheme for such a purpose proved to be. Mr. Verity's portrait was photographed by Mr. H. S. Mendelssohn, of South Kensington.

Mr. J. J. Stevenson, F.R.I.B.A., F.S.A., was a pupil of the late Mr. David Bryce, R.S.A., of Edinburgh, and of Sir Gilbert Scott. After spending some time in Italy, France, and Germany, he designed, in partnership with Mr. Campbell Douglas, at Glasgow, from 1860 to 1868, many churches and mansions in Scotland. In 1870 he settled in London, building for himself the Red House on Bayswater Hill, the first in the so-called Queen Anne style erected in London; and, while partner with Mr. Robson from 1870 till 1875, assisted him by designing in a similar style the exteriors of some of the earliest schools built by the London School Board. At the meeting of the Conference of British Architects in 1874, he read a paper on this style, advocating its greater suitability over Gothic for modern domestic use, an opinion which subsequent experience has justified. Since 1875 he has carried out numerous buildings in London and the country, including houses in Lowther-gardens for Col. Makins, M.P., the south side of Cadogan-square, the greater part of Kensington-court, No. 1, Fitzjohn's-avenue; Munstead, Surrey; business premises at Glasgow, and at Fenchurch-avenue, in the City of London; houses at Oxford, the restoration of St. John's College there, churches at Crieff and Perth, the University Laboratory, and new buildings at Christ's College, Cambridge, and houses there; and he has been appointed by the Senate of that University architect of the Sedgwick Memorial of Geology. In 1879 he furnished designs for the fittings and decoration of the saloons of the Orient Company's new steamer, the *Orient*, the first occasion probably in which an architect was employed for such work: and since then he has designed the fittings of the *Austral*, *Ormuz*, and other steamers. In 1879 he published a book on "House Architecture," advocating the use of

the various forms of "impure" Classic for modern houses in preference to other possible styles, and treating of their planning and sanitary and other requirements. He has contributed several papers to the *Transactions* of the Royal Institute of British Architects; one in 1875 against the late Mr. Fergusson's view that the hope of architecture lay in the abolition of architects; in 1877 on "Architectural Restoration," criticising the prevalent method of restoring old buildings; and again in 1881 on our duty of treating them as historical documents, combating especially Sir Edmund Beckett's views and his work at St. Alban's. The photograph which we reproduce is by Mr. Thomas Fall, of 10, Baker-street, W.

## CARPENTRY AND JOINERY.—XXVII.

## WINDOW-FRAMES.

IT remains yet to be explained, the manner in which window-frames are fixed when the joiner undertakes this part of the work.

It has been already stated that sometimes the bricklayer or mason builds them in, as also the door-frames, during the progress of the building. Whilst in nearly every case all door-frames, except those occurring in partitioned walls, are built in; yet only in the very commonest class of building is this the case with window-frames. Now supposing that the stone sill upon which the sash-frame is to rest is *set*, the next thing to have done is the *screeding*, as it is termed in some localities, at least, that is, a thin layer of plaster is put on the part of the *reveal* which the frame is to rest against. The way in which the

avoid difficulties which would otherwise arise by the frames not being in the same straight line. When a stone reveal occurs no screeding is needed, but some inequalities may require dressing off. The joiner now either takes a light lath and cuts it to the length of the space there is between the jambs where the frame in hand is to be put, and tries if the opening is parallel by testing it in several places with this lath. He then applies this lath to the head and sill, cuts off any extra length there may be on these as *horns* over and above what will go in readily, the frame is then tried in to see that the margin of the brick or stonework is equal on each side of the frame; if not, the necessary change must be made. The next step is to see whether there are

pieces in *above the stiles*, say, 1 1/2 in. thick, and the breadth equal to the width of the top inner casing. (It is not unusual to put these pieces in when the frame is being made so as to nail the side and top casing to where the heading between these occurs.) Having attended to this and the case in hand, being one of the frame resting upon the stone sill *pure and simple*, a layer of white-lead is put along beneath where the sill of the frame is to rest. It would be well just to trace a line along to serve as a guide in spreading the white-lead. Having then the white-lead spread, the frame is put in position, and a stay placed against it; the distance between the top of the frame over the stile and the lintel is measured, and two wedges got out and driven in. Fig. 191 shows this. This, of course, is done at both sides. The one wedge is placed in with the butt end of it towards the brickwork, and the other one is driven in until it is thoroughly tight. This latter wedge must have a bluff point, so as not to catch at the point before it is *tight home*; both sides should be wedged as evenly as possible. The frame should be tested as to its being level and plumb both ways. It should be tried diagonally, to know that it is square for the sashes (that is, both diagonals should be equal). When all this has been seen to, the wedges driven in above the stiles are side-nailed through to the lintel, and

FIG. 190.

FIG. 192

3" SCALE

screeding is done is by putting two laths with straightened edges, *plumb up* the reveal at right angles to the face to be plastered, allowing them to project sufficiently for the layer of plaster and this layer should be as thin as possible, covering of course all inequalities of the brickwork.

Fig. 190 shows by part plan and elevation what is being described, the heavily inked portions being the wood. The laths are kept in position by stays or braces shown in elevation; they are shown sloping so as to indicate that they are jammed tight between the laths so as to keep them hard against the brickwork; a plasterer then puts on the plaster and draws a straight edge down along both plumb laths to scrape off the surplus plaster which projects beyond the line of lath. When the plaster has *set*, the braces and laths are removed, and the putting in of the frame proceeded with. Where there are several frames on the same side of the room all required to be finished alike, a *chalk line* should be put along the wall so as to guide in putting the *screeding laths* parallel from it, and which will

unless timber not dry has been used, there is no risk of such a frame being blown in during a violent hurricane or storm. Of course, additional help in the direction stated is obtained by fixing the finishing of the window; but, as will be shown presently, some windows have finishing of a very meagre description, so that it is better to take secure steps at the very outset. This is the principle of fixing sash frames when the joiner has to do it; and other than square frames will be fixed in similar manner. Segment, semicircular, and other curve-headed frames will be tested to the springing of the curve, in order to find out if they are square for the sashes.

Sometimes glazier's putty is used instead of white lead for bedding the sill of the frame, and *lime putty* has even been used in very inferior buildings. It is to be understood that what is required is to keep out dampness, so that the joiner can judge for himself from what has been stated which will serve the purpose best; but usually the specification fixes the matter, so that

the joiner who carries out the letter of the law has no choice.

The *grounding* for finishing of windows has already been treated of, and will not again be touched upon except as it may be hinted at when the fixing of finishing is dealt with. And now the fitting of sashes may have a passing mention; in many cases these are fitted into the frames in the workshop, but sometimes for the reason that the frames are urgently required, they are not so fitted, the frames being sent off and the sashes not made for a considerable time afterwards. The *batten slips* or staff beads are taken out of the frame, at least the stile ones, also the two parting beads are taken out of the stiles, and the top sash tried as regards its width, and how it *squares* with the head of the frame; the *horns* may be cut off, but before doing so it would be just as well to make sure that the two sashes, when placed in position, are sufficiently long for the frame. This being known, and the horns cut off, the sill portion of the sash may be fitted, and in doing so put into the groove for the parting beads in each stile two pieces, say 3 in. or 4 in. long, so as to stop the sash from falling out of position until it is fitted. Usually the sill of the sash is worked to fit the sill of the frame nearly before the sash is wedged up, leaving only for the joiner who fits the sash the cutting off of the horns and working the bottom ends of the stiles of the sash straight through with the sill, then trying if it fits the frame-sill, making the necessary alteration if any is required. In cutting off the horns and working the ends of the stiles, assistance is obtained by fitting a template to the sill of the frame and laying it on the stiles of the bottom sash, and marking them for cutting and working. When the bottom sash has been thus fitted, and the place marked to which the meeting-rail reaches, the top sash can be finally fitted, as there is less labour in taking a little off the top of the sash than off the sill, which is usually bevelled and double-rebated. A prop can be put under the top sash to keep it up, so as to try in the bottom sash, in order to see that the two sashes fill the frame satisfactorily. One other point: if the sashes are to be painted, there should be allowed for *freedom* in the width as much as would allow the blade of a 6 in. square to move up and down between the stile of the sash and the stile of the frame at each side, also a little less at the top and bottom; this, of course, is allowance for, say, four coats of paint, and to allow the sashes to move freely up and down when suspended. If the sashes and frames are of hard wood, and polished or varnished, less *freedom* will serve. When the sashes are glazed they are weighed, in order to know the amount of weight required for their suspension. Supposing a sash to weigh 20 lb. or 40 lb., then two 10 lb. or two 20 lb. weights would be required to suspend that sash (single). Sash-weights are familiar to most, if not all, joiners, and are usually either lead or cast iron. The weights usually in demand are kept in stock, others have to be ordered, and are cast specially to the order for shape, &c. The joiner can readily in an emergency cast lead weights for himself by making a pine box, into which he can put his pattern of the weight required, and pour in liquid *plaster of Paris*, which will fill the space around his pattern, and if all this has been satisfactorily done, he can cast as many weights as he requires after he has removed his pattern; he can even saw off what there is over the weight required, if his casting is too heavy. But to go on with the hanging or suspending of the sash. The matter of grooving the sash for the cord has been dealt with previously; but as there are several ways of grooving practised, it may be well just to give an illustration of the different sections.

Fig. 192 shows three methods, each of which are used in different workshops, the one on the right-hand side is compound, the square portion of the groove being for the wheel of the axle-pulley, and the concave portion for the *sash-cord*. Take out the *pocket-piece* from the frame, as it is by that opening the weight is inserted; then have what is known in some districts, at least, by the name of a *mouse*, which consists of a piece of sheet lead—say, 2 in. by 3 in.—with a hole in it for a piece of cord, which put through the hole. Let the cord be from 7/2 in. to 8 in. long; double the lead over, forming a roll of it sufficiently small to drop over the wheel of the pulley, which it will more readily do if curved to nearly the curvature of the wheel. Drop the

mouse over the wheel, letting it down behind the stile in the space for the sash weights, keeping hold at the same time of the extreme end of the cord. When the lead (mouse) has arrived opposite the pocket hole, the joiner puts in his hand and pulls it out. Before doing so, however, he attaches the cord to the end of the *sash cord* which he is going to suspend the weight with, and having done so he pulls until he has got the sash-cord pulled through the pocket-hole, when he attaches the weight, putting on a secure knot, and then he pulls the sash-cord the reverse way until he has got the sash-weight into the place provided for it. He is now ready to cut off the cord, having the weight attached as soon as he knows its proper length. To find the length to cut the sash-cord to, proceed as follows: First of all, for the top sash, and supposing it to be the case that the cord is just to be nailed to the sash, not knotted, mark on that face of each sash stile which is next yourself when the sash is in position the place where the ploughing or grooving for the sash-cord ends; now put the sash into the frame, and let this top sash be as low down as it can be put, then transfer the marks on the sash stiles to the frame stiles, and this will be the length of the cord. But for this to be utilised, having the cord with the weight attached in the position previously described, pull the cord until the weight is hard up against the axle pulley on the inside, then let it lower back, say 1 in. or 1½ in., and either put a round plug of wood in the hole of the pulley to jam the cord and keep it in position until the cord is cut and fastened to the sash being kept to the mark which was made upon it (the sash) at the extremity of the groove; or if the pulley stiles are pine, a fine nail can be driven through the cord and a little way into the stile to hold the cord; the nail can be drawn out when the cord is fastened to the sash. This process is repeated for the other side. The operation of getting the cord through the pulley and attaching the weight is the same for the bottom sash. A mark is put upon the bottom sash at the end of the groove on each stile, and when the weight has been drawn up, as described for the top sash, the cord is cut off to this mark at each side and nailed to the sash, the same precautions being taken to prevent the weights from falling until the cords are fastened to the sash. The top sash is first suspended and tried, then the parting beads are put in and the bottom sash weighted and tried, and if found all right, bring it out and ease out the parting beads one at a time and put in the pocket pieces. Let the bottom sash back into its place again, and put the batten slips (staff beads) into their places and permanently nail them. In ordinary cases flat-headed nails are used for fastening the cord to the sashes. When the sashes are weighty, better cord is used, and a special fastening having three points used to fasten the cord to the sashes.

The case of knotting the cord has been treated of slightly, under which circumstances the cord will be so much longer as is required for the knot. Let it be understood distinctly, when it is intended to knot the cord, a groove, say, 9 in. long is made in each stile of the sash distant from that from 4 in. to 6 in., according to the weight of the sash, a 1½ in. or 1¼ in. hole is bored in each stile sufficiently deep to admit of putting the knot of the cord into. The connection between the groove and the hole is made by boring with a long *screw bit* large enough to freely admit the cord used, boring slightly on the incline, so as to get into the centre of the depth of the hole for the knot; the cord is pushed down through this hole and knotted, and the knot on the cord hammered into the hole, with the end inside, no nails or other fastening for the cord being required.

There are steel tapes and copper chain of peculiar construction also used for suspending sash weights. Instructions are usually furnished with these, and the particulars given above will enable the joiner to carry out any special instructions issued with a particular patent.

#### CAST IRON AND ITS APPLICATION FOR ARTISTIC PURPOSES.

A LECTURE on this subject was given before the Society of Arts on Tuesday evening by Mr. W. R. Lethaby, and was illustrated by numerous examples. The author claimed for cast iron a position in serious art, and said he proposed by an examination of specimens to

arrive at an appreciation of the metal, and of certain methods of manipulation. By a careful selection of the forms and treatment suited to the structure and texture of the material, and its application to commonplace needs, artists had in all ages given the charms of fitness and honest simplicity, and accepting the comparative valuelessness of the metal, had used it for the vehicle for slight thoughts and slighter execution. By far the greatest of our designer sculptors, the late Alfred Stevens, worked long and thoroughly as a modeller from cast iron—from no choice of his own it may be, nor choice probably of subject; and yet by far the most popular work of modern sculpture, the little lions on the outer rail of the British Museum, of which so many other artists were glad to keep casts by them as examples of breadth and style, were only cast iron. The torch-holders on the top of the same screen with reliefs of heads surrounding the bowls were also his. Table supports, stoves, and grates also occupied his care. Although the invention of casting in iron was made very early, and was referred to by Pausanias, Pliny, and other classic writers, there was no evidence to show that casting iron was practised in England before the Middle Ages, nor at what time it was then introduced. M. Viollet-le-Duc supposed that it was known in France in the 13th century, to which date he attributed a fragment at St. Denis. In the 14th century cast-iron artillery was probably founded all over Western Europe, and it is likely enough that this may have introduced the furnaces into Sussex. Magnificent bronze sculptures were cast here in the 13th century by Torelli, the artist of the lovely Queen Eleanor and Henry III., at Westminster Abbey. There were in Sussex and Kent many iron grave slabs, the earliest of which, that at Burwash, was almost certainly in work of the 14th century, and many dated examples of subsequent ages existed, one of the latest known being one of 1752 at Wadhurst. In the great open fireplaces where logs burnt on the hearth of hall and kitchen, cast-iron slabs called firebacks were put against the wall behind the fire. They were found alike in France, in the Low Countries, and in England, and invariably charged with some device, arms, inscription, badge, or a scene Scriptural or classic, an allegory or a fable, something to suggest a thought, as the pattern adorned the opening in summer, or burnt red-hot behind the winter fire; all these things were books. In the best of these the relief was kept flat, and modelled but slightly, never being rigidly carved with sharp definition. The ornament in Gothic example always gave some suggestion of life and growth, roses or vines, and letters were often reversed, and so used as parts of designs. The later firebacks were very numerous, although for the most part now in "collections" instead of adorning the cottage hearth or the hall for which they were specially made, for hardly any exact duplicates occurred, and in very many instances the arms or an inscription identified the former owner's family. The coat-of-arms were large or small, with or without supporters, or a number of small shields filled up the whole space; many had the Royal arms, others horsed warriors galloping in attitudes expressive of a consciousness of the converging gaze of nations. Many of the subjects were drawn from the Biblical or mythological story, and some devices referred to the Stuart Kings. The actual achievement in the poorest of these firebacks was low enough. Some were, in fact, almost grotesque, but yet they all had that fresh touch of a real motive—a direct reference to some expressive gesture or pleasant object; all treated with great simplicity, and that instinct for balance and spontaneous fitness and freedom in the ornament, without any forcing the material or obtrusive display, which was the mark of the traditional crafts. The system was, almost without exception, to keep a flat field, which showed in pretty wide spaces all over, and the modelling on this was in low relief—the less the better—evenly balanced and of equal length throughout, so that the light was distributed in narrow edge lines right over the surface. To sum up in a word, a decorated piece of iron, instead of a cast sculpture of bossy high lights, and the ground lost in the weight of the relief. The firedogs or andirons which accompanied the backs on the hearth made a parallel series. De Caumont and Viollet-le-Duc cited examples of late 14th century and early 15th century in France. Many of later date in England still carried on the Gothic forms. From an arched

base, sometimes cusped, sprang a stem, which carried a small shield, a capital, or a head. These were interesting historically, but were not the models we should follow. We had seen enough of the "Gothic revival" in cast iron; what we wanted was new thought based on practical needs, and the Gothic spirit of a search for beauty untrammelled by formulas. Still later examples of the 17th century were figures or "terms," the best designed of which were signed "Carron." To be successful the figure should be just a solid post without weak projections or detail. Perfectly plain turned vase and baluster forms on a base, or obelisk-like posts on pedestals, were also used, and were as appropriate as any. Simplicity alone never failed; it was the charity of design that would cover a multitude of sins. To aspire was well, but to aspire vulgarly and fail vulgarly was to make art an offence and distaste. Mr. Lethaby described the grates that fill the older houses in London as, for the most part, of excellent design, and remarkable examples of careful casting; some were, he found, quite plain, with just a moulding or two, and others were fluted and beaded all over with tiny ornament on flat surfaces; the simplicity of the general forms saved the ornament from being worrying. Having alluded appreciatively to the cast iron of China and Japan, with especial reference to the sword hilts, teakettles, and vases from the latter country, the lecturer turned to the wider aspect of the subject, remarking that he was not one of those who wished to see in iron a material for a new architecture; nor did he wish its extended use, rather inversely a smaller field, but that field as full of flowers as might be. But while we used iron in some degree, while we even needed iron, while it might grow into wider necessary use, we should lend what grace we might to it, so that if obtained with cost, the greatest of all cost—an unkindly labour—it might not be misspent and more than spoilt, used to insult a trained understanding in the brutality of its vulgar insolence. Bad art went with bad commerce, bad goods, bad society. It was true in every department of work, of all materials, and of every form of pay, what the ironmaster said to Emerson:—"There's always good iron to be had: if there's cinder in the iron, 'tis because there was cinder in the pay."

#### BOOKS RECEIVED.

*Engineering Estimates, Costs, and Accounts*, by A GENERAL MANAGER (London: Crosby Lockwood and Son), is a guide to commercial engineering, or the preparation of estimates for engineering work. The author very justly remarks that there is need of the sort of information he endeavours to supply. In these days of keen competition those firms who tender require to know the cost of materials, how to convert them with the least labour, and leave a profit. Sometimes, again, an engineering contractor has a complete detailed specification and drawings from which he can frame his tender, and he will then have to get out his quantities and price them; at other times he will have to prepare his own plans and specification and will have more scope for exercising his tact. The author's work is intended to supply the data for calculations of this kind and the preparation of estimates by giving hints as to the calculation of weights of the iron or other materials, for which purpose many useful formulae and data are given. Thus is shown how the weight of a crank shaft is taken out by dividing it into component parts, such as the cylinder and crank-pin ends, web of crank, &c. The estimation of workmanship requires more experience and knowledge, and the information given under this head is of value. The making of various estimates to obtain the gross cost is considered in detail. The method usually followed is to price the materials and labour at certain rates, which include the cost of material and workmanship, and the working expenses and profit. The most correct mode is to take out the quantities of weight and the items of workmanship, and against them put the amounts of wages that are paid. The author gives examples of both kinds of estimating. All kinds of engineering, including millwrights' work, belt pulleys, hydraulic presses, pumps, brickmaking machinery, valves and taps, engines, boilers, &c., are dealt with, and tables of prices and wages are given. The work will be of much value to engineers and managers generally in preparing estimates.

*Heating by Hot Water*, by WALTER JONES (London: Crosby Lockwood and Son), is a reprint from our contemporary, the *Ironmonger*. Mr. Walter Jones's little book will be of service to architects, builders, and others who require practical advice on the preparation of their specifications. To the practical hot-water engineer the suggestions and information supplied cannot fail to be of use. The advantages and disadvantages of the high-pressure and low-pressure systems are pointed out succinctly, and the author shows that the low-pressure system has considerable advantages over all other methods of heating, as it can be applied to any kind of building, and its cost is less than that of any other system. The risks of accident are reduced to a minimum, and the temperature is easily distributed and regulated. Any kind of fuel can be used. The author, who evidently understands his subject, practically deals with matters of detail; he points out how to insure a rapid circulation by either increasing the height of the two columns or the length of the pipes, or by using pipes of smaller diameter. The rule for determining the motive-power is very simple, and is explained by an example. The causes of failure, which are numerous, are one by one explained. Many types of boilers are illustrated and their merits discussed, pipe-joints are dealt with, and patented methods are described. The heating of churches and public buildings is briefly referred to, and many forms of hot-water coils, radiators, and coil cases are illustrated. The author believes that the objectionable draughts found in churches and other buildings can be remedied by heating with high-pressure tubes the upper strata of air, putting low-pressure pipes near the floor, both being heated from one fire. The remarks on bath apparatus, swimming and Turkish baths, are worth reading, and the book will repay a careful study by those interested in hot-water heating. — *The A. B. C. of the Law of Landlord, Tenant, and Lodger*, by FRED. WETHERFIELD (London: 2, Gresham-buildings, E.C.), is a new shilling manual by the well-known legal editor of the *Weekly Times and Echo*, which cannot fail to be of service to everybody. It includes leases, repairs, and agricultural holdings; and there are some useful forms of agreement and notices to quit appended. Mr. Wetherfield, unlike some legal writers who profess to write popular legal manuals, does not start by taking too much knowledge for granted on the part of his readers. He supposes them really to know nothing, and he keeps well in mind the practical points that his long experience has led him to anticipate as likely to arise in connection with house hiring. Every man who lets or takes a house should get this cheap and useful shilling's-worth, and auctioneers, house agents, and others will find it handy—especially as regards the forms of agreements and notices.

#### CHIPS.

The Countess Cadogan laid on Saturday the foundation-stone of the Central Public Library for Chelsea. The building will be Queen Anne in style, and is being erected in Manresa-road, from plans by Mr. J. M. Brydon, selected in competition, and illustrated in our issue of June 7, 1889. The outlay will be £10,000.

At the meeting on Friday night of the Lancashire and Cheshire Antiquarian Society, held in Chetham College, Manchester, a paper on "The Mouldings of the Gothic School of Architecture," was read by Mr. John Brooke, architect, of that city.

The late Mr. William Billings, of Leicester, has bequeathed £5,000 for the benefit of the Leicester Permanent Art Gallery.

A Local Government Board inquiry was opened at Burnley on Friday, with reference to an application by the corporation to borrow £4,820 for extending the gasworks, completing the waterworks at Caul Clough, which will cost £130,000, as against an estimate of £60,000. A small sum is also included for town-hall purposes.

At the Central Criminal Court on Friday, Frederick Clark, aged 49, a surveyor, was convicted with another man of having uttered a forged Chilian bond of the value of £1,000, and was sentenced to 18 months' imprisonment with hard labour.

At a meeting held in the schoolroom of All Saints parish, Hereford, last week, it was decided to take steps for the restoration of All Saints Church, in accordance with a report submitted by Mr. John Oldrid Scott, F.S.A., whose estimate of the outlay was between £5,000 and £6,000.

## Building Intelligence.

**COMBERMERE MEMORIALS.**—Messrs. Douglas and Fordham, architects, of Chester, have prepared designs for two obelisks which are to be erected on two of the largest estates in Cheshire—Combermere and Eaton. The Combermere statue is to be erected in accordance with the will of the late Mary, Viscountess Combermere, who died on the 30th August, and bequeathed £2,000 for the purpose of raising a monument "as a memorial of the military successes and private virtues" of her deceased husband. The site chosen for the obelisk is an elevated piece of ground called Mount Pleasant, situated about a couple of miles from Wrenbury railway station. It will have an altitude of 100ft., and from its commanding position will form a conspicuous feature in the landscape for many miles. It will bear heraldic emblems on the base, and suitable inscriptions, recording the achievements of the distinguished soldier. The obelisk to be erected in Eaton Park will be of somewhat similar character, 85ft. in height, and occupying a position at the junction of the two main avenues about a quarter of a mile from the front of the hall.

**LEEDS.**—The foundation stone of St. Aidan's Mission Church, Roundhay-road, Leeds, was laid on Saturday. The buildings will form only the beginning of a larger scheme, which embraces the provision of a future church and vicarage. The premises now in course of erection comprise a large schoolroom on the ground floor, with three classrooms, a tea-making room, and lavatories. On the first floor, which will be reached by a wide open stairs, as well as by a smaller inclosed relief stairs, will be a large room to be used for the present as a temporary church, and ultimately as a parish room. The buildings are exceedingly plain, as they will in the future be largely concealed by the church. They are being built in brick, with stone dressings and tiled roofs. The architects are Messrs. Chorley and Connon, of Park-row, Leeds, and the builder is Mr. Arthur Schofield.

**LONDON COUNTY COUNCIL.**—At Tuesday's meeting of this body, the Bridges Committee reported that they had submitted the question of the proposed communication across the Thames at Blackwall to Mr. J. Wolfe Barry, and he considered a tunnel practicable, but suggested a high-level bridge. The committee were of opinion that as the road of the bridge would have to be at least 21ft. above high-water mark to admit of vessels passing under it, a bridge was, considering the low level of the land on either side, out of the question. They therefore proposed: "That the Council do proceed with the formation of the tunnel authorised by the Thames Tunnel (Blackwall) Act, 1887—namely, by three lines of borings, one being for foot passengers and the other two for vehicular traffic." It was agreed to adjourn consideration of the report for a fortnight. Mr. A. R. Binnie was appointed chief engineer, in the stead of Mr. Clement Dunscombe, resigned through ill health, at a salary of £1,500 a year. Mr. Binnie had been, it was stated, for many years engaged in engineering work in India, and since his return had been for 15 years engineer to the Bradford corporation.

**NEWCASTLE-ON-TYNE.**—After extensions and improvements, the Northern Conservative Club, Pilgrim-street, was formally reopened by Earl Percy on Friday. The works have been effected from the designs of Mr. James C. Parsons, of Grainger-street, Newcastle. The principal alteration has been the addition to the building of a suite of offices to the north of the original premises, having a frontage of 19ft., by a depth backwards of 125ft. The entrance hall has been widened from 6ft. 6in. to 9ft. Additional space has been afforded on the north side upon the ground floor for a smoking-room, 30ft. by 18ft., with a lavatory behind. On the first floor the extensions consist of an enlargement of the dining-room, which is now 58ft. in length by 19ft.; a private dining-room, 18ft. by 20ft., the enlargement of the serving-room, formation of a new staircase to the billiard-room, and additions to the lift. The billiard-room on the second floor is now 58ft. in length, and the roof has been raised from 9ft. to 27ft. by the removal of the attics above. There are also on this floor a card-room, measuring 18ft. by 20ft., and an extra billiard-room, 22ft. by 22ft. In the attics there are four bedrooms and a bathroom. Externally the

club premises appear almost as a new building. The contractor for the structural alterations was Mr. Edward Weatherley.

#### COMPETITIONS.

**DORSET COUNTY LUNATIC ASYLUM.**—Sixteen designs have been submitted in competition for the enlargement of this asylum. The committee of visitors have appointed Mr. C. H. Howell, their professional assessor, to advise in the selection. Mr. Howell is the consulting architect to the Commissioners in Lunacy.

**MANCHESTER.**—The trustees for the new Wesleyan chapel at Plymouth-grove have decided to accept the plans of Mr. Curwen, of London. The style adopted is Early Geometrical Gothic, on the lines of the St. John's Chapel, Sunderland, by the same architect. The new chapel will provide accommodation for 750, and cost about £8,500.

#### CHIPS.

Mr. Bertram William Cook, the late engineer to the Rochdale Canal Company, was presented last week by the employés and friends connected with the company, with a case of drawing instruments (manufactured by Mr. W. F. Stanley, of London), on his retirement after 11 years' service. Mr. Thomas Holden, the oldest mechanic in the company's employ, made the presentation, and Mr. Cook suitably replied. Mr. Cook is about to leave the country for Mexico, where he has received an appointment to construct some extensive reservoirs.

The committee for filling the Cook memorial window in St. Stephen's Church, Bristol, have selected, from four designs submitted in competition, that sent in by Messrs. A. O. Hemming and Co., of St. Margaret-street, London, W.

Earl Manvers cut on Friday the first sod of a new railway, which is being constructed for the Manchester, Sheffield, and Lincolnshire Railway Company, from Beighton Junction, in North Derbyshire, to Chesterfield. The railway is the first section of a new line which was authorised by an Act of last session, by means of which the Manchester, Sheffield, and Lincolnshire Company will effect a junction with the Great Northern Railway at Annesley, and by the exercise of running powers obtain a direct route between Sheffield and Nottingham. The new line, including ten colliery branches, will have a total length of 35½ miles, and it traverses a district which is thickly dotted over with collieries. Mr. W. E. Stubbs is the engineer.

The Jubilee obelisk on the summit of Dennis-hill, Padstow, has just been completed. It is 50ft. in height, and built of solid granite. The architects are Messrs. Henry and John Paynter Hamilton, of London, and the builder is Mr. Nicholas Robins, of Wadebridge.

Wadham College, Oxford, has recently become possessed of the old Communion table at Iminster Church, at which, in all probability, Sir Nicholas and Dorothy Wadham must have been in the habit of communicating. It is of oak, handsomely carved, and undoubtedly good Elizabethan work. A stone altar has been substituted at Iminster, and the Communion-table will now be placed in the college chapel.

The Pontypridd section of the Barry Railway has been formally taken over by the company by Mr. J. Robinson, their resident engineer. Mr. J. W. Szlumper was the contractor.

The works in connection with the Pocklington Water Company were commenced last week by Mr. Thos. Bell, contractor, and will be pushed on as rapidly as possible, so that the inhabitants may have a supply by the beginning of the ensuing summer. The engineers are Messrs. Fairbank and Son, M.Inst.C.E., of Westminster, S.W., and Driffield.

The Russian Minister of Domains, with a view to preserving the valuable and extensive walnut and palm forests of the Caucasus, has just placed an export duty of 50 copecks per poood on all wood exported of those trees.

A new block of buildings for females has been added to the county pauper lunatic asylum at Clifton, York, at a cost of £4,500, and from plans by Mr. Walker Stead, county surveyor for the North Riding.

John Hill, a surveyor, of Broadstairs, late of Brighton, was at the Westminster Police-court on Friday committed for trial on a charge of embezzling a sum of money, and with endorsing a cheque in the name of H. Scharien and Co., builders, for whom he had acted as agent.

The chantry at Wakefield, known as "the Chapel on the Bridge," and which is closely identified with the Wars of the Roses, was formally reopened last week after being partially restored.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.) To India (via Brindisi), £1 10s. 4d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING for TWENTY-FOUR WORDS, and Sixpence for every eight words after. All Situation Advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page advertisements and alterations in serial advertisements must reach the office by Tuesday Morning to secure insertion.

NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XLII, XLVI, XLIX, L, LI, LIII, LVI, and LVII may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

G. A. K. (The bond of mullion you send us will be considered in our next article on "Brickwork.")

Intercommunication.

QUESTIONS.

[10224].—**Sound.**—The rooms in a building to be erected abroad are to be divided by 3in. timber-framed partitions covered on both sides with 5th match-boarding, and it is proposed, in order to prevent sounds passing from one room to another, to fill in the cavity between match-boarding with sawdust; but I am of opinion that the air space would be a better non-conductor than the sawdust. Perhaps some of your readers would state their experience?—H. M. C.

[10225].—**Echo.**—We have a large room used for lectures, &c., 78ft. by 35ft., and 30ft. to springing of roof, windows about 10ft. from ground. When full there is a bad echo, some speakers being quite inaudible. We have tried a series of wires across the room, but these are not successful. Can some of our readers kindly suggest a remedy, or what would be the best books to consult on the subject? I should say there is a platform 4ft. high running right across the room. The roof is Gothic and steep in pitch.—C. C.

[10226].—**Wholesale Contracts.**—Being very interested in the articles already written on the subject of "Wholesale Contracts," and not having knowledge of the system of master-builders as described by your able writer "Goth," I should like to ask him for a little more light on this system. Does he mean that the master-builder only acts for the employer? On whose credit then are all materials ordered, and who keeps the "builder's yard" with its almost inexhaustible supply of all sorts of odd materials and scaffolding? Then how does the builder get his remuneration—by commission? In that case, then, I presume he might have several jobs in hand at once. As "Goth" thinks that in this direction there is some chance of improving the present unsatisfactory state of things, he would greatly oblige by giving a little more information to—A YOUNG BUILDER.

[10227].—**Natural Bed.**—What is the correct way of placing the bed of a stone in a joggle-jointed arch? The usual method in an arch not joggle-jointed is to put the bed perpendicular to the face. If this is done when the arch is joggle-jointed, it seems to me the projecting portion would be of little use; for if any weight came upon it, it would very likely slide off. Now if the bed was placed the other way, would it not be much stronger?—MINERVA.

[10228].—**Roofs.**—In calculating weight of roofs, what weight per foot is usually taken for slate roofs?

How are the sizes of roof timbers calculated for towers? How are the sizes of riveted girders and stanchions calculated—some shaped stanchions carry weights better than others? In calculating the crushing weight, are angle pieces added to the sectional area?—A MEMBER OF THE B.N.D.C.

[10229].—**Velocity and Volume of Sewers.**—The accepted method in practice of ascertaining the flow (i.e., the velocity and volume) in sewers, both egg-shaped and circular. Will some correspondent kindly give an example, worked out in detail, say, of a 3ft. 9in. by 2ft. 6in. egg-shaped sewer, and of a 12in. pipe sewer?—NOVICE.

REPLIES.

[10220].—**French Chateaux.**—The following are a few of the most noteworthy and typical of the châteaux of France:—Carcassonne, Early 13th century; Pierrefonds, 1390, restored by E. V. le Duc; Meillant, near Saint-Amand Martrond, 1443; Amboise, end of 15th century; Chénouceaux, beginning 16th century, Renaissance; Chaumont, 16th century; Blois, 15th, 16th, and 17th centuries, west block by T. H. Mansard; Azy-le-Rideau, early in 16th century, Renaissance; la Youardaye, Morbihan, 1530; St. Germain en Laye, 16th and 17th century, Ducerceau, C. Metzeau, Mansard, and Millet; Fontaine le Henri, near Caen, latter part 15th century; St. Ouen, Compiègne, 18th century, Y. A. Gabriel. The département of Loir-et-Cher is particularly rich in châteaux, dating from the time of François I.—F. ELIE GAY, Bath.

[10222].—**Billiard-Room Floor.**—I should recommend, if possible, the floor to be a double floor, and that binders should be placed 6ft. or 7ft. apart, the joists being notched to them. Rolled-iron joists would be one means of economising depth. If single joists are used, the strutting should be solid, and three courses ought to be used. The bolts suggested would hardly be of much service.—G. H. G.

CHIPS.

A new parochial hall for St. Thomas's parish, Winchester, will be opened to day (Friday) by Lord Northbrook. It has been built from designs by Messrs. J. Colson and Son, of that city, by Messrs. J. Fielder and Son, builders, also of Winchester. It is constructed of local brickwork, is 8ft. 6in. long by 25ft. broad, and will seat 400 persons.

At a monthly meeting of the Pontefract Town Council on Friday it was decided to ask the Local Government Board to send down an engineer to examine the Roall water scheme before incurring further expense on the present site at Roall.

By a majority of one the Lancashire County Council have decided to appoint a Medical Officer of Health, at an annual salary of £800.

The Townhead School, erected by the Kirkintilloch Burgh School Board, was formally opened on the 6th inst. The school has accommodation for 650 pupils, including special accommodation for cookery and a laboratory. The total cost, including site and furniture, will be about £6,500. The architect was Mr. Malcolm Stark, jun., I.A., Glasgow.

The Normanton Local Board have accepted tenders for the paving of the township from end to end.

Two courses on sculpture, of three lectures each, will be given shortly at the Royal Academy by Mr. A. S. Murray, keeper of the Greek and Roman antiquities at the British Museum, and Prof. J. H. Middleton, of Cambridge. Mr. Murray's subject is "Sculpture in Greek Temples," and his course will begin on Monday next; Prof. Middleton's subject is "Florentine Sculpture in the Fourteenth and Fifteenth Centuries," commencing on Friday, the 28th inst.

Messrs. Atkinson Bros., stained-glass artists, Newcastle, have been commissioned to fill with stained glass the west window of the Presbyterian Church, Jarrow.

Messrs. Leslie and Reid, civil engineers, of Edinburgh, have prepared plans and specifications for the landward portion of the Water of Leith pumping station and sewage works, and tenders have been invited for the construction of the portion between Slateford and Coltbridge. The works are to be completed for the two local authorities by the end of next year.

At a meeting of the Brockwell Park Purchase Committee, held on Saturday, it was announced by the Executive Committee that a contract had been entered into for the purchase of 78 acres, at a cost of £117,000. Other expenses increased the outlay by £5,000, the whole amount of which had been raised, the contributions including a donation of £36,000 from the committee for the abortive scheme to purchase Raleigh House, Brixton-hill. Arrangements will be made for opening the park as soon as the enabling Bill has received the sanction of Parliament.

Mr. Harry Bucknell, Stud.Inst.C.E., of Stratford-on-Avon, has been appointed assistant engineer in the Public Works Department of Ceylon. Mr. Bucknell was a pupil of Mr. A. T. Davis, Assoc.M.Inst.C.E., county surveyor of Salop, and formerly borough surveyor of Stratford-on-Avon.

LEGAL INTELLIGENCE.

**A BUILDER AND HIS APPRENTICE.**—At the Westminster County-court, on Tuesday, Judge Bayley and a jury were occupied for a considerable time in hearing the action of "Gibson v. Barton." The plaintiff, a builder and contractor, of Vauxhall Bridge-road, sought to recover £51 18s. 2d. as damages "for loss of services by reason of the absence of defendant's son from his employment on various days from 1885 to 1889." Mr. Tickell, in opening the case for the plaintiff, said the action was brought against Edmund Barton, the father of Edmund William Barton, who was an apprentice in Mr. Gibson's service, for damages for refusing to work and for absenting himself from work, which he sometimes did for a week at a time. During six years he had refused to work 281 hours, and had absented himself 588 hours. His Honour observed that there was no claim in the particulars for refusing to work, and declined to amend. The learned counsel, continuing, said the boy received 5s. a week for the first year, which rose by increments of 2s. until it reached 14s. per week. His client had paid the lad for work he had never done, and he now claimed its return. The plaintiff gave evidence in support of this statement. Cross-examined by Mr. Gore, who appeared for the defence: The lad entered his employment as an apprentice for six years in 1884, and left in November last. He did not know the defendant was a lodging-house manager only earning 30s. a week. Last October he wrote to Mr. Barton telling him he was indebted to him for over £120 for damages and the boy's absence, and work and material spoilt by him. The lad's first year's wages were at the rate of 1 1/4d. per hour, exclusive of meal time, and he was now charging 6d. an hour for that time. When the boy's wages were 12s. a week, or 2 1/2d. per hour, he charged for the purposes of this action 8d. an hour. Plaintiff further admitted that he never gave the boy a holiday during the whole time he was with him. His diary would show that the lad was away four days when ill, because witness told him not to come to work till he was better. The boy was away ill sometimes, but had never stayed at work after eight o'clock at night. By His Honour: He had brought a similar action to this some time ago, and was successful. Benjamin Woodward said he had been a builder for forty years, and he considered the plaintiff's claim very reasonable. Mr. Gore, in addressing the jury for the defence, characterised the case as a scandalous one. At the end of the time of the boy's apprenticeship, a claim was sent in amounting to £15 less than the total sum of the lad's wages during the whole of the time he was in the plaintiff's service, and then when this action was brought it was reduced to £51. Most of the time the boy was away was on Bank Holidays, and on other days he was ill. If a proper calculation was made, it would be found that the whole sum the plaintiff was entitled to, at the rate the boy was paid, was two guineas. The jury said they did not want to hear any evidence for the defence, as they were perfectly satisfied, and should give a verdict for the defendant. His Honour gave judgment for the defendant, with costs.

The Council of the Surveyors' Institute have just published a statement of reasons against the provisions of the 28th (Betterment) Clause of the Strand Improvement Bill, and express their opinion "that the proposals of the clause are inequitable, and would be troublesome, costly, and irritating if attempted to be put into practice."

At a meeting of the Liverpool city council on Wednesday the resolution of the Art Congress held at Edinburgh in October last, expressing a hope that the council would reconsider their decision to discontinue the decoration with sculpture of the panels on St. George's Hall by Mr. Stirling Lee in accordance with his designs, was brought under consideration. A letter was read from Mr. Rathbone, a member of the council, agreeing to be permitted to undertake the cost of completing the four remaining panels according to Mr. Lee's contract with the corporation. A letter was also read from Alderman Samuelson suggesting that the work might be completed in bronze. After a discussion the matter was referred to the Finance Committee to report upon.

The Committee of the Iddesleigh Memorial Fund report that the total subscriptions to the fund amounted to £2,181 17s. After defraying the expenses of the statue by Sir J. E. Boehm, which has been erected in the Central Hall of the Palace of Westminster, a sufficient balance remained in the hands of the committee to enable them to commission Mr. Edwin Long, R.A., to paint a replica of his portrait of Lord Iddesleigh. This has been presented, on behalf of the subscribers, to the trustees of the National Portrait Gallery, who have added it to the collection.

The National Bank of Wales, Cardiff branch, is warmed and ventilated by means of Shorland's patent Manchester stoves, supplied by Mr. E. H. Shorland, of Manchester.

## Our Office Table.

A YOUNG woman named Elizabeth Vincent was, at the Richmond Police-court on Wednesday, charged with shooting Major Isaacs, M.P., F.R.I.B.A. He stated that he had been intimately acquainted with her for some years; that he had settled money on her child, and had given her funds to enter into business; that she invited him to her house, produced a paper, and said she would shoot him if he did not sign it. He added that she demanded that he should sign certain cheques. He declined to do so, and tried to take the pistol from her; but she pointed it at him and fired. He received the bullet in his arm, where it still remains. The defendant, who said it was an accident, was remanded in custody, and the chairman of the Bench advised her to obtain legal assistance.

The official report of the commissioners who were appointed to inquire into the cause of the fall of Messrs. Templeton's mills at Greenhead, Glasgow, on November 1st, has just been issued. After reviewing the evidence given and the theories propounded to account for the fall, the commissioners (Col. Malcolm, R.E., and Mr. W. Wybrow Robertson, of H.M. Office of Works) state that the materials and workmanship employed in the building were of excellent quality, and that no shortcoming in this respect contributed to the accident. The disaster was caused, they found, owing to the weakness, from want of lateral support, of the brick wall, which was wrecked by the oblique pressure of the wind, and led, by the dragging forces of the joists, to the simultaneous collapse of the front and rear walls. Had the building been completed, they believe no wind pressure likely to occur in Scotland could have destroyed it. Having alluded to the contradictory character of the evidence as to who was the responsible designer of the building, they add:—"We are not seeking to apportion the responsibility, but a practical lesson of some importance is indicated—viz., that when an architect and engineer are employed in designing a building, which may in many cases be desirable, they should not follow one another and act without concert, as in this case, but they should act together either as collaborators or as principal and assistant, the responsibility in either case being perfectly clear."

The seventh annual dinner of the Clerks of Works' Association was held on Monday evening at the Holborn Restaurant, under the chairmanship of Mr. MacVicar Anderson, V.P.R.I.B.A., and brought together a much larger number of members and visitors than any previous gathering of the kind. The health of "The Architects and Surveyors" was proposed by Mr. J. H. Smith, and acknowledged by Mr. Ralph Nevill, F.S.A., and Mr. J. Gandy. The toast of the evening—"Success to the Association"—was proposed from the chair, and acknowledged by the President, Mr. Linn Dillon. The other toasts included "The Honorary Treasurer," Mr. J. Oldrid Scott, proposed by Mr. J. Brady, and acknowledged, in Mr. Scott's absence, by Mr. J. P. King; "The Worshipful Company of Carpenters," proposed by Mr. F. Dashwood, Secretary, and acknowledged by Mr. Banister Fletcher, Master of the Company; and "The Committee of the Association," proposed by Mr. A. Ritchie (Messrs. Stephens Brothers and Co.), and responded to by Mr. R. Wheeler, Vice-President. It was stated that the Association was prospering, and increasing in numbers and strength.

MR. ROWLAND PLUMBE, F.R.I.B.A., has drawn up a report on the requirements for a polytechnic for Battersea for the executive committee of the South London Polytechnic Institution. The site is between Battersea Park-road and Battersea Park, being isolated on every side by roads, and contains an area of 2 acres 29 p. On this it is proposed to erect a structure accommodating 5,500 students, of whom 4,500 would belong to the technical department. The scheme provides a hall capable of holding 1,500 persons, and swimming-bath and a gymnasium. The main building is to include a technical library, three music and elocution rooms, with provision for lectures and classes. An upper floor is to contain the chemical laboratories, the photographic rooms, the art schools, and the drawing classes. The workshops are arranged in a wing, which

practically detaches them from the main building. Social, reading, and club rooms are located in the main block. Space is allotted for engines, boilers, and dynamos, the adoption of the electric light being strongly recommended. Separate reading and club rooms are to be provided for women. The estimated cost of the building is £40,000, a sum which applies to a structure of the plainest and most utilitarian character. The appliances and fitting up are reckoned at £8,000, the cost of the land £9,000, and sundry items £3,500, making up a total of £60,500. The Charity Commissioners have promised £2,500 a year for the endowment, if the committee can raise £60,000, and of this latter sum all but £12,500 has been obtained. As soon as the scheme of requirements is finally settled, a selected number of leading architects will be invited to send in plans for the actual building; but Mr. Plumbe will not take part in such competition.

THE *Baltimore Sun* announces the recent death, from old age, of Mr. George Clark, architect, a native of Bristol, England, at the Church Home, North Broadway, Baltimore. Mr. Clark, who was 89 years of age, was for 43 years with the late Sir Gilbert Scott, and superintended the decorations and arrangements of St. James's Palace on the occasion of the first ball ever attended by Queen Victoria. As superintendent of construction for Sir Gilbert Scott, he had charge of work on the royal palaces at Windsor, Frogmore, Buckingham, and St. James. He restored the cathedrals at Chester, Lichfield, and Ripon, and large churches in Yorkshire, at Croydon, Newcastle-under-Lyme, St. John's, Leicester, and over forty churches elsewhere. Among the many private residences he built were those of the Duke of Buccleugh, the Earl of Cadogan, and of Mr. Asheton Smith in Hyde Park-gardens. The old gentleman took much pride in speaking of his architectural work, and of his contact with and rubbing against Royalty and the Peerage. He leaves one daughter, the wife of Mr. Crook, late organist at St. Paul's Episcopal Church in Baltimore.

A SYSTEM by which the use of the sextant and slide-rule is much extended was described to the members of the Royal Scottish Society of Arts, on Monday evening, by Mr. W. B. Blaikie, of Edinburgh. The system, Mr. Blaikie stated, had been of enormous service to him when engaged in Government survey work in India, and though the results obtained by it were not meant to rival the Ordnance Survey in accuracy, for many practical military and exploring purposes the method was accurate enough. By means of a plumb "bob," which might be used either hung from the finger or the end of a walking stick, the pocket sextant could be converted, for field purposes, into a level, a chronometer, or an instrument for measuring slopes. Mr. Blaikie went on to explain a method of using the sextant as a range-finder, illustrating how this instrument and slide-rule could be worked together. Some discussion followed the reading of the paper, and at the close the chairman, Lord Kingsburgh, in moving a vote of thanks to Mr. Blaikie, incidentally mentioned that the present Earl Wemyss had introduced a range-finder, which consisted of a telescope with a number of lines drawn across the outermost glass. By ascertaining the number of lines which covered the object looked at, one was able to arrive at an approximate distance.

At a meeting held at the University College, Nottingham, on the 6th inst., Prof. Garnett delivered a lecture on "Sanitary Plumbing," and Sir Philip Magnus presented certificates of Registration granted by the Plumbers' Company, London, to a number of master and operative plumbers in the district. Sir Philip Magnus, in presenting the certificates, said nothing could be more successful than the organisation of plumbing classes had been throughout the country during the past few years. In the session 1885-6 there were 342 plumbers' students in these classes, in the following year the number increased to 403, in the year after to 695, in the year 1888-9 to 1,043, while during the present session no less than 1,217 student plumbers were receiving efficient instruction in the technical and theoretical branches of their craft. He ascribed this success mainly to the fact that the workmen had taken the greatest possible interest in the movement, and both the masters and the operatives were fully alive to the great importance of technical education.

## MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Royal Institute of British Architects. "Building Legislation," by J. Slater, B.A. 8 p.m.  
Royal Academy. "Sculpture in Greek Temples," by A. S. Murray, of the British Museum. 8 p.m.  
Liverpool Architectural Society. "Quantity Surveying," by H. L. Beckwith, F.S.I. (hon. sec.) 7 p.m.  
Leeds and Yorkshire Architectural Society. "Conditions of Modern Architecture in Towns," by Halsey Ricardo. 7.30 p.m.  
TUESDAY.—Institution of Civil Engineers. Papers on Waterworks at "Shanghai," by J. W. Hart; at "Tytam, Hong-Kong," by J. Orange; and "Yokohama," by J. K. T. Turner. 8 p.m.  
Manchester Architectural Association. "The Ventilation of Public Buildings," by F. R. Farrow, of London.  
Civil and Mechanical Engineers' Society. "Italian Water Supply," by A. Fairlie Bruce. 7.30 p.m.  
WEDNESDAY.—Society of Arts. "Organisation of Secondary and Technical Education in London," by Prof. Silvanus P. Thompson, D.Sc. 8 p.m.  
Carpenters' Hall Free Lectures. "Modern Sanitation," by Prof. W. H. Corfield. 8 p.m.  
THURSDAY.—A. Lyric Club. Concert at the Mona Hotel, Henrietta-street, W.C. 7.30 p.m.  
FRIDAY.—Royal Institution. "Magnetic Phenomena," by Sheldford Bidwell, F.R.S. 9 p.m.  
Institution of Civil Engineers. "American Locomotives," by C. N. Goodall, Stud.I.C.E. 7.30 p.m.

## CHIPS.

Mr. R. G. Baldwin, a builder, was summoned to the Westminster Police-court on Wednesday to show why he should not make certain alterations in some houses at Chelsea, as required by the Metropolitan Building Act. It was stated for the prosecution that the houses were so constructed as to be very dangerous in case of fire. Mr. D'Eyncourt ordered the defendant to remedy what was complained of within twenty days, and allowed costs.

The 47th annual congress of the British Archaeological Association will be held at Oxford in July next, under the presidency of Earl Carnarvon.

Mr. Aspinall, of Cardiff, has been elected surveyor of the Stroud local board of health. One hundred and ten candidates offered themselves for the post.

A new altar and reredos dedicated to Our Lady have been consecrated in the R.C. Church of SS. Mary and John, at Wolverhampton. They are Gothic in style, and are executed in Caen stone, the altar slab being supported in marble shafts.

The widening of the North Devon line between Barnstaple and Nunderleigh, and the Ilfracombe line from Barnstaple to Braunton are approaching completion, and the remaining section between Morthoe and Ilfracombe has been commenced. Messrs. Lucas and Aird are the contractors.

The Ruskin Museum at Sheffield, which is being removed to new quarters, is to be opened about the middle of April by the Earl of Carlisle.

Longtown Bridge, Cumberland, has just reopened after widening, from plans by the county surveyor. The work has included the widening of the bridge and approaches by 9ft. on the north side for a distance of 450ft., and the repair and heightening of the parapet on the south side, at an estimated cost of £2,300, and has been carried out by Messrs. Marshall and Sons, builders, of Hawick, for the sum of £2,221 10s.

The Children's Hospital in Great Ormond-street, W.C., is about to be enlarged, at a cost of £15,000, by the addition of a jubilee wing, from plans by Mr. Charles Barry.

The London School Board resumed last week the debate on the motion for an independent examination by an outside architect of all the buildings erected by the Board. As an amendment, it was proposed that the Government should be asked to appoint a Committee to inquire into the matter. In the discussion the relative expediency of the inquiry being conducted by a Select Committee or by a Royal Commission was considered, and the amendment asking for a Committee was carried.

A new music-hall has been erected at Llanfair, and special attention has been paid to the ventilation, which is carried out on the Boyle system.

Mr. Richard Crittall, of 20, Baker-street, W., and 34, North-street, Manchester, has just issued a useful and comprehensive catalogue of fittings for the electric light, which will be serviceable to all architects and builders.

The Darlington School Board have accepted tenders amounting to £3,314 for the erection of a boys' school to accommodate 390 pupils, in accordance with plans, &c., prepared by Mr. Thos. W. Robson, architect, Darlington.

## Trade News.

### WAGES MOVEMENTS.

**HULL.**—The bricklayers' labourers have declined an offer of an advance of  $\frac{1}{2}$ d. per hour as from May 1, demanding that the rise be conceded at once. The strike, therefore, continues.

**NEWCASTLE-ON-TYNE.**—At a crowded meeting of the Newcastle district of the National Association of Operative Plasterers, on Saturday, it was decided to ask the employers to grant an advance of 1d. per hour, making the wages 8 $\frac{1}{2}$ d., to take effect on May 3. They have taken a vote of the association, and it has been decided to give them support if needed.

**Holloway's Pills** are especially recommended to all annoyed by tender bowels, a source of constant weakness, if not indicative of danger. Diarrhoea, flatulency, nausea, spasms, and indigestion yield to the extraordinary power of this purifying medicine exerts over digestion and those subservient functions which extract the food's nutriment for the body's maintenance.

**DOULTING FREESTONE.**  
**THE CHELYNCH STONE.**—The Stone from these Quarries is known as the "Weather Beds," and is of a very crystalline nature, and undoubtedly one of the most durable Stones in England.

**THE BRAMBLE DITCH STONE** is of the same crystalline nature as the Chelynych Stone, but finer in texture and more suitable for fine moulded work.

Prices, and every information given, on application to CHARLES TRASK and SONS, Doultong, Shepton Mallet, Somerset. London Agent:—Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.

### HAM HILL STONE.

The attention of Architects is specially invited to the Durability and beautiful Colour of this material. Quarries Well Opened; Quick Despatch Guaranteed; Stonework Delivered and Fixed Complete. Samples and Estimates Free.

Address:—

**THE HAM HILL STONE COMPANY,**  
NORTON, STOKE-UNDER-HAM, SOMERSET.  
London Agent:—  
Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.C.

## GEO. FARMILOE & SONS,

Lead, Glass Oil, Colour, and Varnish Merchants.

ALL LETTERS TO OFFICES AND WAREHOUSES:—

**34, ST. JOHN STREET, WEST SMITHFIELD, LONDON, E.C.**

Lead Works: Island Lead Mills, E.  
Sanitary Appliances and Plumbers' Brass Work Factory: Eagle Court, Clerkenwell, E.C.  
Stained Glass Works: 109, St. Martin's-lane, W.C.  
Wharf: Queen's Wharf, Wapping Wall, E.

Telephone No. 3614.

Telegrams:—"Faraday, London."

**FARADAY and SON'S**

# To Municipal Authorities, Engineers, and Surveyors.

## JENNINGS' PATENT URINALS

FOR PUBLIC THOROUGHFARES AND RAILWAY STATIONS,

Have been adopted in all the principal European Cities. They are particularly adapted for public use, being simple in construction, strong, and most economical as regards the water supply.

## JENNINGS' STONEWARE DRAIN-PIPES

Have been specially selected and adopted, after severe tests, by the South Australian Government for the drainage of Adelaide. The Sockets and Pipes are made in one piece under great pressure by Steam Machinery from the finest selected Poole Clay taken from Beds on the works, and, by hydraulic testing, have been proved superior to any other pipes in the market. Prices and particulars can be obtained from

## WINDOWS, THEIR DISTRIBUTION AND DESIGN.

THE distribution and design of windows, upon which so much of the comfort, appearance, and expression of a building depend, have hardly received the attention and study from architects that their importance requires. Appearance rather than utility has been considered in their design, or we should not see the hapless arrangements one often meets—buildings in which the rooms have been fitted to the windows of a façade, instead of contrariwise, the windows being arranged for the room. The old classical formula of dividing an elevation into equal-spaced bays, each with a window, and distributing the piers and openings by the pair of compasses could not lead to any other result than that of the first-mentioned, in which the cross-walls or partitions between the rooms were determined entirely by the openings. Resulting from this arrangement we observe one or two windows lighting a long room at the end: one of them may be close to the corner, and placed without any reference to the height of apartment. In some rooms the opening is too small, in others a great deal more light is admitted than necessary. By the second arrangement, the windows are planned to agree with the rooms, and the elevation is broken up in such a manner that the want of uniform division becomes less noticeable.

The subject may be treated—first, as regard the position of the windows in the room, and second, with respect to the elevation. Lighting is the first and primary condition, and ought to be studied in reference to the room. The slight attention paid to the question is proved by the indifference shown by architects to the aspect of windows. Though the aspect is not a matter of choice, being generally fixed by site, yet the importance of making it a consideration cannot be denied. How unreasonable it is, for instance, to find the largest windows placed on the side of a building which receives the greatest quantity of sunlight, the smaller ones being located on the darker side. In this climate, for example, the large windows are better placed on walls facing the north and westerly sides, and the smaller ones on walls facing the south and east. Southerly windows having the maximum amount of the sun's rays for the longest time need not be so large as those on the north side. Strange to say, theorists who have laid down rules for window openings have lost sight of aspect in giving an invariable size for windows, hence Palladio's rule is of little use in this gloomy climate, and so are most of the empirical rules that have been given. Besides climate and aspect there is prospect, which ought to be considered. In this murky climate of ours where wet and foggy seasons are the rule, it is wise to make our windows large, even if we have to regulate the admission of light by other means; but of size we shall say more presently.

The shape and dimensions of a room ought to determine the window opening. It is well known that if we place a window at the end of a narrow room it will be more satisfactory than if placed in the centre of the longest side: the light will fill the room better and there will be no dark corners; but if it occupies the long side of room there will be dark ends and the space will be much more lightly lit. When a room has its longest side to a front wall, as very often happens, wide windows are a necessity. To avoid the

semi-gloom and partial lighting of a centre window, the lighting area ought to be distributed evenly; thus a room 30 or 40 ft. in length should have a series of five window openings, an uneven number being preferable to prevent a shadow in the centre. On the whole, a general maxim to be remembered is that windows are more desirable at the end of an oblong-shaped room than at the side, and that, other things being equal, a less amount of window opening is required at the end than at the side. Many architects have an idea that in a building of several stories the same size of opening should be used in every story, and the hard-and-fast rule of observing the same height and character of the window throughout an elevation is a dangerous precedent with those who are more willing to follow a rule than to be guided by reason. It seems equally necessary to insist as a rule, that the height of a window should be regulated by the height and length of the room. The rays of light coming through the window at a certain angle ought to penetrate as far into the room as possible; but at an angle of, say, 45°, direct rays would only penetrate into the room a distance equal to the height of the window from the floor. Hence the importance of keeping windows high, and to make them reach very nearly to the ceiling. We have noticed unpardonable errors in the placing of windows. Not only have we seen the windows placed altogether in one corner of a room, or badly distributed, but the heads of them so low that the further end of the room is left in gloom, all from the desire to keep the windows equal in spacing and height throughout the elevation.

Secondly, considered with respect to elevation, the first principle that seems to be ignored is that the elevation ought to be regulated by the apartments and their lighting. The general rule is to make the elevation as pleasing as possible, to put in the windows so as to balance or to distribute them more for the sake of ornament than for use, and to make the plan fit as far as it can. If the principle with which we started was kept in view, of arranging the rooms with their proper windows, and then the elevation set out and designed to meet those data, the result would be more satisfactory. As long, however, as architects will draw out their elevations first before they have perfected their plan, the errors of badly-designed windows will remain a standing rebuke to the mode adopted. To discuss the matter more in detail would exceed our limits; but it is not difficult, after the plan of the window openings has fairly been considered, to draw an elevation that will agree with any trifling irregularity of spacing. A break, or a projection, or a quoin can be arranged to occupy the wider spaces of wall pier; and to strike a balance between the two sides of the façade, if a symmetrical elevation is required, is not so difficult a matter after all. A little readjustment of plan will be found to meet the elevation. When the windows of two adjoining apartments happen to come far apart, and it is not desirable to have a break, the expedient of pilasters may come to our aid. Should the intervening space be narrow, it is often possible to group the windows externally. In short, by breaks, pilasters, grouping, and other means, the inequalities that occur in the spacing of openings are readily overcome.

We have, in considering plan, forestalled much of what we might have said under size of windows. Theories have been proposed for the purpose of determining the area or windows for certain rooms; some of these theories, like those of Vitruvius, Palladio, and Sir W. Chambers, are arbitrary, or are based on the requirements of an Italian climate; others are empirical and far-fetched. Perhaps the most reasonable rule that has been proposed is that in which the area of the aperture is based on the cubic space of the

apartment; thus the square root of the cubical contents in feet of the room will give the area of light required, which can be distributed by one or more windows of any desired proportion. The rule does not tie the architect to any height or width of aperture, which may be regulated at his will. As we have hinted, the principal thing to remember is that of allowing the light to penetrate the room, and to preserve an agreeable proportion. Wide single windows are objectionable and ugly, the only mode of making them agreeable being to subdivide the space by mullions or piers. In streets facing lofty buildings, or in gloomy neighbourhoods, the size of opening should be increased; it should also be recollected that what is a suitable size for a domestic dwelling-house will be inadequate for a house of business or a show-room. Where a prospect is desirable, as in a private residence, the width of a window may be increased, or the area of openings distributed by having two or more windows in the wall. The prevailing use of quarry glass is a strong reason for making the openings a little larger than the rule affords, rather than smaller.

The subject is one very intimately related to expression. A many-windowed front has an open and urbane appearance, though excess of apertures may lead to the extreme of weakness. A front with few and small openings suggests austerity and gloom. These opposite ideas or sensations are created by the proportion existing between the plain surfaces and the voids simply; but there are other impressions, the result of the distribution and variety of the openings themselves. The different kinds of impressions are well illustrated in the Italian façades where austerity may be seen in such buildings as the Riccardi Palace, Florence, and the open fenestration in the Venetian buildings such as the famous Library of St. Mark, at Venice. Again, variety in the forms of windows is seen in the courtyard-elevation of the Doge's Palace, where pointed and circular openings in various positions are met with. But of the latter kinds of expression we would refer to three—(1) varying the openings and spaces horizontally, (2) varying the sizes of openings vertically, and (3) varying the shapes of openings.

These different ways of giving variety are often employed. Thus the windows of one level, or story, may be grouped or set out at unequal distances. In other buildings, like the south façade of Somerset House, an oblong opening on the ground-floor has over it a square mezzanine opening; above this the principal story has the pedimented oblong window, and over this a square aperture. Inigo Jones and Sir William Chambers were masters of fenestral composition, and their works are worthy of a patient study as elucidating the art of varying the openings, both in size and shape. Of modern buildings, Bridgewater House, the Reform Club House, both by Sir Charles Barry, illustrate the variety obtainable in Italian façades. One kind of fenestration is particularly objectionable: the repetition of the semi-circular or pointed opening in each story. The repetition of three-light windows is also to be avoided; but in groups, separated by plain single openings, they add value and variety. In this, as in all other things, there should be unity in variety, or a confused heterogeneous composition is the result. We may probably see more windows in Northumberland-avenue than in any other London street of the same length. The buildings are lofty, and their architects have had recourse to various means of giving variety and of avoiding monotony. The great corner hotel partly facing the Strand is perhaps the most marked instance of the heterogeneous fenestration. Cut up horizontally into numerous small stories, the windows have an isolated and higgledy-piggledy look, which they need not have had

if a little more grouping together and gradation had been attempted, or a line of large openings had occupied the principal floor. In the Avenue Hotel a proper connection has been observed. With numerous openings it is not difficult to avoid repetition, if only the stories as they rise preserve a kind of rhythm in the proportion and shape of the apertures.

#### STREET RECONSTRUCTION AND NEW SITES.

THE demolition of old streets and buildings in many parts of London has not in every instance resulted in an improvement to the neighbourhood, for, owing to the rights of ownership and vested interests, the authorities have been baffled in their attempts to let or sell vacant sites for building purposes. The consequence has been that in various parts of the metropolis are to be seen vacant sites inclosed that are little better than refuse receptacles, surrounded by a class of old and often tumble-down premises in a ruinous condition that ought to have been cleared with the houses to which they backed. In Charing Cross-road several sites of this kind may be met with, and many more may be seen in the lines of new thoroughfares and widenings on the north and south sides of the Thames. On some of the vacant sites, such as those in the Charing Cross-road at the back of the National Gallery, theatres have been erected; on others, large blocks of business premises. Several of these open sites are admirably adapted for public buildings, such as technical schools, polytechnic institutes, and free libraries. They, however, lie under the ban of private rights. The ominous "ancient light" claim has a blighting influence on speculators and builders. To turn for a moment to the extent of the Metropolitan Improvements—and how much more might have been accomplished, if under a more comprehensive jurisdiction street improvements had gone hand in hand with the endeavour to provide public institutions and sites for special buildings! As these things are now managed in England, one authority has powers granted to it to acquire property for the formation of new streets or for widening; but it has no voice in the question of selecting sites for public buildings. The consequence is an immense amount of unnecessary friction and clashing of interests when any definite scheme is brought forward; but what is more to be deplored is that in discussing any proposed line of street or widening, no provision is made for any possible public improvements, so that should a valuable site be within reach, it is allowed to escape attention—no attempt is made to include it in the scheme by a slight deviation in the line. The only task of the committee seems to be to draft the Bill, to settle claims, and to let surplus land, regardless of what might be done to make the thoroughfare an architectural ornament. For example, we cannot but believe a great deal more might have been made of the widening of Gray's Inn-road at the Clerkenwell-road end and northwards. The question of dwelling accommodation for the working classes displaced was one of the obstacles. The widening of Upper-street, Islington, which has cost a very large sum for compensation alone, the Hammersmith improvement, the demolition of houses near the Elephant and Castle in the Walworth-road offered favourable opportunities for acquiring corner sites for free libraries, technical schools, and other buildings of general public interest. Working-class dwellings have been erected on some of the sites, but to the detriment of the surrounding properties. In every case of street improvement opportunities are offered for acquiring properties at the junctions of other streets; but in how few of them do we

find that advantage has been taken?—the sites in many cases having been let at their market price for shops and ordinary dwellings, instead of being retained for the many more important class of public buildings.

Several open spaces at the corners of thoroughfares are to be noticed in different parts of the Metropolis, such as the corners of Waterloo and Westminster-roads, and it may be opportune to inquire whether the regulations of the County Council will at all touch them? The first important point in connection with corner sites is the line of frontage; the next is the elevation. Both these matters ought to receive the attention of the authorities. When a corner site is opened by the removal of old buildings, something may be done to improve the curve or the angle between the two roads. A circus suggests itself to most people as the right thing to make, and no doubt in crowded parts a good circus is a boon; but as they are generally managed the space thrown open may become rather a danger or a nuisance than otherwise. A circus with the whole area covered by tramway lines is objectionable and dangerous; people are afraid to cross, especially timid people and country visitors; in fact, there is more risk of accidents in a large area for vehicular traffic than in a more confined space. We have ocular demonstration of the fact in the recently-opened area in Piccadilly-circus, which is now being utilised as a sort of refuge. The authorities of our public improvements do not seem to think there are any other ways of utilising the space than to construct underground conveniences and paved refuges with ornamental lamps. Surely the space in some case can be left unpaved, and turfed or planted, with far more desirable results than paving the whole surface and putting a few posts round. Of course, statuary is one way of occupying a space; another would be to erect covered shelters on the areas, that could be made ornamental as well as useful. We know the architectural beauty and interest of some of our old city market crosses, such as those of Salisbury, Chichester, Shepton Mallet, and Malmesbury, with their central pillars surrounded by groined structures open all round. These would form a good type for the modern public shelter in our crowded streets; but very often it would be better to allow the corner plots to remain as they are where four or more streets meet, than to enlarge a space that would become a source of danger, if only the designs of the buildings were carefully considered. No one is responsible, however, for the elevations; and the ordinary square or level-topped buildings are erected, which make the site less attractive than it was when the old buildings, with their irregular skyline, gave an individuality to the place, which is lost when stereotype uniformity has been substituted.

Clause 70 of the London County Council (General Powers) Bill bears on the question of "sites not previously occupied in whole by buildings." It is to the effect that no person shall extend any building or erection upon a site of this sort "in such manner that any part of the external wall of such extension shall be in any direction at a less distance than 20ft. from the centre of any roadway used as a carriage-way, or than 10ft. from the centre of any footway used for foot traffic only, without the consent in writing of the Council, &c." We certainly cannot quite understand this clause, for it appears to give a building owner the right to extend his external wall in a very undesirable manner in streets of over 40ft. in width. Say, for example, the street is 50ft. or 60ft. wide; then, according to this clause, a builder may extend his outer wall to within 20ft. of the centre of roadway, and he will thereby be a gainer to the extent of 10ft. or 20ft.—surely never contemplated.

#### THE SYMBOLISM AND ICONOGRAPHY OF EARLY AND MEDIEVAL CHRISTIAN ART.—XI.

By GEORGE ASHDOWN AUDSLEY, F.R.I.B.A.  
(Author of "Handbook of Christian Symbolism," and several works on Architecture and Art.)

##### AUREOLE AND GLORY.

THE word *Aureole* is frequently met with in writings upon certain branches of art; but not always with its correct significance. It has very often been used instead of *Nimbus*, to designate the attribute placed around the head, in the manner already described in our preceding articles. In its correct significance the term is used by archaeologists and students of Christian Iconography to designate the attribute which surrounds the entire figure in representations of the Persons of the Holy Trinity, their symbols, the Virgin Mary, and certain other personages and symbols. The *Aureole*, as met with in works of Christian art, represents a halo of light emanating from and surrounding the entire body with a soft effulgence; or a fiery emanation of vivid rays or flames, which assume straight or wavy forms, arranged in radiating fashion. Other forms obtain which cannot well be included in

FIG. 29.

either of the above classifications, but these shall be described as we proceed. From the general definition given, it will be observed that the *Aureole* is similar to the *Nimbus* in its origin and nature; differing from it only in form and in being applied to the entire body instead of being confined to the head. The *Aureole* generally extends beyond the *Nimbus*, embracing it and the entire body in its field; but instances exist in which the *Nimbus* is entirely or partially outside the margin of the *Aureole*.

"The word *Aureole*," says Didron, "is derived from the Latin word *aureola*, the diminutive of *aura*, a breeze, a zephyr, a breath; *aura* also signifies day and light because the coming light of day is ushered in by the morning breeze, or perhaps bright rays and flame, which are as it were the efflorescence of light and day. *Aura* comes from the Greek word *αἶψα*, a gentle wind zephyr, exhalation, vapour, in short *aurora*. These significations may be reduced to one only, luminous breath—indicating precisely the nature of the *Aureole*, which is itself a flame as expressed in iconographic art by undulations surrounding the body, or by lines representing rays of light. The *Aureole* and the *Nimbus* are identical in their nature which is that of a transparent vapour or solid light. The luminous halo described by

FIG. 30.

Virgil as encircling the goddess Minerva, and which he expresses by the words '*nimbo effulgens*,' was unquestionably an Aureole rather than a Nimbus.

"*Jam summas arces Tritonia, respice, Pallas  
Insedit, nimbo effulgens et Gorgone savâ.*"

As it is almost impossible to fully describe and illustrate the Aureole proper without treating of the Glory also, of which it is so important an element, we propose to describe them together in the course of the following notes. The term *Glory*, in the nomenclature of Christian Iconography, signifies the combination of the Nimbus and the Aureole in connection with a single personage, by which the most exalted state of deification, divinity, majesty, and power is expressed. As in the case of the Nimbus, the Aureole is used alone, when it becomes, so far as signification is concerned, a Nimbus for the body. Portraits of sacred personages accordingly appear with the Nimbus alone, with the Aureole alone, and, lastly, with both the Nimbus and Aureole.

Christian artists no doubt derived the Aureole, as they did the Nimbus, from Pagan sources; they certainly found, as has just been shown by the short quotation from the "*Æneid*," allusions in the Classic authors which suggested the appropriate idea of surrounding celestial beings with luminous clouds or emanations. They found, however, nothing but suggestive ideas, and these supplied no authorities for its shape and

artistic treatment. Such being the case, Christian artists may fairly claim the merit of having originated the several forms which the Aureole assumes in their iconographic systems. These, as will presently be shown, were arrived at in the process of adapting the attribute to the different postures and outlines of the figures invested with it; and in the hands of the artists of the Middle Ages it assumed numerous shapes which were commonly of some symmetrical or severe geometrical outline.

The Aureole appeared in Christian art at a much later date than the Nimbus; indeed, the latter attribute had become thoroughly established in Christian Iconography, and had assumed all its more important and typical forms and treatments before the Aureole was introduced. We may further remark that in Western or Latin art the use of the Aureole was comparatively short-lived, and that at no time does its adoption appear to have been a settled matter. In the art of the Greek Church, however, few changes have taken place, and both the Aureole and Nimbus have continued to be painted, on ancient and traditional lines, down to the present time.

The first idea of the Aureole was evidently that of luminous vapour, or clouds which received and localised, as it were, the light or radiance which issued from the body. St. Dionysius the Areopagite, in his *Celestial Hierarchy*, speaks of the angels as being

robed in clouds; and just as Christian artists readily adopted his teaching with reference to the *Orders* or *Choirs* of angels, so would they freely adopt the idea of enveloping them in luminous clouds. The peculiar spirit of Mediæval art, however, was averse to the representation of anything so immaterial and undefined as a vapour or ever-changing cloud; and only approached the task in the most guarded and conventional manner. Accordingly, in the earliest examples of the Aureole, we find it rendered as a distinct form, with boldly-defined boundary lines; assuming the office of an attribute, like the Nimbus, about the signification of which there could be no uncertainty. The original idea of clouds is not altogether lost sight of, however, in these conventionally rendered Aureoles; indeed, we find in some examples that the clouds are freely expressed. In these the clouds serve as a sort of fringe or border outside the field proper of the attribute. We give an illustration of one of these cloud-fringed Aureoles in Fig. 29, from a window of the 13th century in the Cathedral of Chartres. The crowned figure represents the soul of St. Martin ascending to heaven. It is surrounded by an Aureole of the most usual form, having a plain field. Outside this is a broad fringe of clouds, rendered in the conventional manner peculiar to the artists of the Middle Ages. Such purely conventional representations of rolling clouds are frequently met with in the 13th and 14th century stained glass and miniatures of illuminated manuscripts. It will be observed that the figure of the soul of St. Martin is not invested with the Nimbus, accordingly it is not yet "in glory."

From the time of St. Dionysius it remained a favourite impression throughout the Middle Ages that the angels moved to and fro, and that the souls of the blessed ascended to heaven in clouds of fiery light. St. Ouen, in his "*Life of St. Eloi*," thus speaks of the resplendent Aureole, the spherical light, the *pharus* which enveloped the soul of the Saint as he ascended to heaven:—"Inter verba orationis flagitatum a superis emisit (Eligius) spiritum. Statim vero cum esset hora prima noctis, visus est subito velut pharus magnus ingenti claritate resplendens ex eadem domo coruscando conscendere, atque inter mirantium obtutus sphaera ignea crucis in se similitudinem præferens, velocique cursu densitatem nubium præteriens, cœli altitudinem penetrare."

We shall, in the first place, briefly review the forms which the Aureole has assumed under the hands of Christian artists, afterwards touching on matters connected with its artistic treatment and its application in iconographic art. Several forms of the Aureole have been introduced, generally designed with the view of suiting the peculiar positions of the figures invested, the elongated and upright forms being, in the generality of instances, applied to standing figures, whilst those in the forms of circles, quatrefoils, &c., are used for seated or half-length figures. In many cases, however, the upright Aureole has also been given to seated figures. An example of the latter treatment is to be seen in Fig. 5 (Article V.), in which God the Father is depicted seated within a lenticular Aureole. The form which has most commonly been adopting for standing figures, and which may be accepted as the characteristic form of the attribute, is that which is outlined by two equal arcs of a circle, touching each other at their extremities, such as the portion surrounded by the clouds in Fig. 29, and that shown in Fig. 30, taken from one of the interesting copperplate engravings in *Il Monte Sancto di Dio*, by Antonio Bettini, of Siena, printed in the year 1447. This form of Aureole has been vulgarly designated the "*vesica piscis*" by numerous English archaeologists. Why it was found necessary or advisable to resort to so remote a source as the bladder of a fish

FIG. 31.

FIG. 32.

for an inexpressive name for the simple pointed Aureole is not easily explained; and, as M. Didron justly remarks, "a term so gross deserves to be expunged from every refined system of terminology." We shall most certainly ignore this inappropriate and vulgar term in our future remarks, using the term *lenticular* instead.

This form of Aureole is treated in various ways, from a perfectly plain field to the elaborately-wrought one shown in Fig. 30. Between these two extremes there are many degrees of richness. In the case of the Aureole in the illustration now under consideration, the field is covered with flamboyant rays, indicative of vivid light and intense radiance, and expressive of the exalted degree of the personage it invests. The figure is that of Our Lord, and He is here represented in a Glory of the most expressive character, for not only are the tri-radiated Nimbus and the rayed Aureole present, but the latter is upheld and surrounded by glorifying angels. On referring to Fig. 5, already alluded to, a different treatment of rays will be observed, although the idea of intense radiance is the same. There are two orders of rays—one directly emanating from the figure invested, and the other surrounding the outer edge of the Aureole as a fringe of light. Here the Aureole proper assumes the form of a framework, with an arched piece across it serving as a seat for the inclosed figure. The whole appears of a very material nature, far removed from the idea of luminous clouds and vapour.

In the accompanying illustration, Fig. 31, we find the same description of frame Aureole, containing a standing figure of our Lord; but devoid of any indication of radiance, and with its material nature heightened by the manner in which it is borne by the six angels. This example is from the *Speculum Humane Salvationis*, an Italian manuscript of the 14th century, in the Royal Library, at Paris. The Aureole in Fig. 30 assumes a certain material character from its well-defined border, and its being supported by six angels. In Italian mediæval art, the lenticular Aureole is almost invariably met with, and with its boundary lines firmly defined, as in the examples above alluded to.

Throughout the miniatures of that wonderful 10th-century manuscript, the *Bene-*

*dictional of St. Æthelwold*, we find the lenticular Aureole used exclusively. In all cases it appears substantial and boldly defined; indeed, in two instances, the artist seems to have endeavoured to convey the idea of thickness by representing the edge nearest to the eye. His imperfect knowledge of perspective, however, has caused him to do this so clumsily that his intention is open to conjecture. We think there is little doubt that he did intend to depict the edge, and, accordingly, the thickness of the Aureole; for, in both the miniatures the figures of Our Lord are represented moving towards the side, carrying their Aureoles, as it were, behind them. This will be clearly understood by referring to Fig. 32, which is taken from the miniature of the Ascension.

FIG. 33.

In the original the Aureole is shown rising amidst clouds, and followed by angels. M. Didron, who was a most enthusiastic student of Christian Iconography, and a very keen observer, does not appear to have met with what we may call the *Aureole in perspective*, for he neither mentions nor illustrates an example in his works. We have no recollection of having seen it or anything approaching it in any work of art save that from which our illustration is taken. There are so many points of resemblance between the Aureoles in this manuscript, excluding this one perspective treatment, and those commonly found in Italian art, that one would almost suppose that it had been illuminated under some direct Italian influence. Its early date (A.D. 963-984), and the peculiar richness of its colouring, rather disprove this supposition. It is generally believed that the illuminator was an Englishman, and if he was subjected

to any immediate influence in his work it is very probable that it was from a Byzantine source. There is much in the art in this wonderful book to incline one to the latter conclusion. Italian manuscripts did not display elaborate detail and rich colouring before the beginning of the thirteenth century. Before we leave the pages of this manuscript, we may remark that in only one Aureole do we find the arched piece which is so marked in Figs. 5 and 31; and then it is neither a prominent feature, nor does it cross the broad portion of the field and pass behind the figure, as in the Italian examples. Instead of this, it is placed close to the bottom of the Aureole, to serve as a rest for the feet. The lower portion of the Aureole alluded to is shown in Fig. 33. The miniature in which this treatment obtains is that representing the Incredulity of St. Thomas.

(To be continued.)

## ARCHITECTURAL BRICKWORK.— XXIX.

### RECESSED ARCHES.

AS an example of recessed arching we may take a semicircular door-head, in which a plain gauged brick-and-a-half arch forms the recess within which is the doorway, having over it an arch one brick thick (sketch 1). These two arches are separate though in contact, and, therefore, it does not follow that the joints coincide. Care is required in cutting and rubbing the arch bricks to the true shape, especially the bedding joints, so that the bricks will bear evenly and not throw an unequal pressure on the outside edge, a fault which, as we have already pointed out, leads to disturbance of the arch. When an arch is recessed by a succession of members, plain or moulded bricks are used, and these may be made to contribute to the depth and richness of the arch. In sketch 2 we show a moulded arch of different shaped bricks, the rings being set one within another, such as we find in ornamental brick archways. To produce a good arch bond in each ring, the bricks are laid as headers and stretchers, or one as a header the full length of brick bonded into the thickness of the wall, as shown in our sketch, and the next one to it as a half-brick, half the length being cut off. As an

sample of an archway of this sort, having recessed members of brick, we may refer the student to the archway over main entrance, courtyard in Layer Marney Towers, Essex, one of the earliest examples of rickwork and terracotta in England, circa 1506. This archway, if we examine it closely, has three distinct rings or moulded members (in addition to the label moulding), forming two hollows, separated by a roll and fllet. Each ring is worked independent of the others, as we shall show by sketch. Very few of these deeply-moulded brick arches are to be met with in this country, though one often sees plain chamfered bricks set in successive rings receding from the face of wall.

#### SPRINGINGS.

Sketch 3 illustrates the manner two cut and rubbed arches abut against each other at the springing of a capital, taken from a newly-erected suburban house. As will be noticed, three or four of the lower arch bricks are reduced in length, a vertical abutting joint dividing the two arches, which are each 9 in. in thickness. Another plan is to put a stone or terracotta springing block in place of the first three or four lower bricks, and to start each arch from a bevelled skew-

back. This plan avoids the straight joint, and makes a stronger abutment over the column; but has the disadvantage of not being a brick-cut arch throughout. It is preferable to cut the bricks to a vertical joint in the way shown than to run the lines of extrados together till they meet, as this would entail not only increased width of abacus, but a deal of fine cutting between the two arches.

#### MOULDED ARCHES.

We show an example of a three-light cottage window from Broadstairs, Kent, in which the mullions and arches over are moulded (4). The bricks are moulded, and the effect is very satisfactory. Sketch 5 is one of the single-light window arches at Layer Marney Towers, and illustrates the mode of jointing the arch bricks in two courses. It will be seen at the apex of arch the key-brick is in one; in the lower ring there is a joint. These windows are admirable specimens of moulded brickwork; many of them have labels. Other details from this noted example of English Renaissance work we shall give.

#### MULLION BOND.

A correspondent (Mr. George A. Kenny, architect, of Ipswich) sends us a plan for the

successive courses of the mullion we described at page 195 in our last article, and we have reproduced his sketches. Referring to our diagram, showing a one-and-a-half brick mullion, he observes: "I consider it to be very bad bond"; and he shows in the sketch we now give what he considers to be the strongest. The sketch of bond we gave was only one mode of constructing a mullion.

We did not say it was the best, or strongest. Few mullions of this size, which have to preserve an external bond, are very good, owing to the absence of a good tie between the front and mid feather. We admit that Mr. Kenny's plan shows a stronger bond, as the tie is better, the whole brick going through to the front on every other course, instead of a mitred brick, as shown on p. 195. There is, however, one objection to the plan, which some bricklayers would consider fatal—the external appearance of bond is not preserved, as in one course there are three headers in a row, and on the other two three-quarter bricks as stretchers. In the plan we gave, which is carried out in numerous windows, the Flemish bond is preserved; it is, moreover, given in some textbooks. We are glad to receive suggestions of improved bond from any correspondent.

#### ARCHITECTURAL ASSOCIATION.

THE fortnightly meeting of the Association was held on Friday evening, the president, Mr. Leonard Stokes, in the chair. It was announced that the second visit for the present session would be held to-morrow (Saturday) afternoon, when Mr. T. E. Colclutt's Imperial Institute would be inspected. An appeal by the hon. secretary to the committee for the restoration of the noble tower of Chewton Mendip parish church was read. The tower shows signs of failure, and Mr. J. D. Sedding, hon. diocesan architect for Bath and Wells, reports that it can be repaired and strengthened at a cost of £750.

#### SOME TYPICAL GREEK BUILDINGS.

Mr. R. ELSEY SMITH, who was elected in 1887 to a studentship at the British School of

Archæology at Athens, read a paper descriptive of his excavations of "Some Typical Greek Buildings," illustrated by plans, measured drawings and sketches, and by a large number of photographs, shown by the aid of the oxyhydrogen light. The lecturer confined his attention principally to those buildings which he thought might be taken as representative of the domestic, secular, and sacred architecture of the Greeks—viz., the Palace of Tiryns, the Propylæa, and the Erechtheion of the Athenian Acropolis. The last of these, Mr. Smith explained, is also a wonderfully beautiful example of the use of the Ionic order, while the second illustrates the very best period of the Doric order, and all three are specimens of the magnificence and freedom of Greek planning. Of these three buildings, by far the oldest is the Palace at Tiryns, though six years ago its existence was unknown, and by most people undreamt of. We will, therefore, consider it in the first place, more especially as we shall discover in it the beginnings of much of the later Greek art and architecture. The citadel of Tiryns occupies a magnificent position near the sea, overlooking the Bay of Nauplia. The rock rises abruptly out of the level plain, and nowhere is there any eminence that in the days before artillery was introduced could command it. The natural features of the rock form the key to its fortifications, which were adapted to it with great skill; they are the most massive of their kind in Greece, and possess several points of great interest. Any student who wishes a more detailed account of the walls or the palace will find it in Dr. Dorpfeld's account of them contained in chap. v. of Dr. Schliemann's "Tiryns." Owing to the form of the rock, three more or less separate forts existed within the outer ramparts; the lower, the middle, and the highest, and crowning the last, and occupying the greater part of it, stood the king's palace. The materials used in its construction were stone, limestone, breccia, and sandstone, clay, either beaten hard or used as mortar or cement, or as sun-dried bricks; lime, and wood; while in the decoration of its surface, plaster covered with coloured decoration, carved alabaster, and almost certainly bronze plates, were employed. The plan of this fortress-palace, though not perfectly preserved, approaches being so, and is far less incomplete than the palaces at Mycenæ or Troy, or the fragments of Erechtheus' palace in the Athenian Acropolis, and all three have many points of similarity both in plan and construction. At Tiryns, having passed through the fortress-wall, we approach the outer gate of the palace. This gives admittance to a large open space, devoid of building. After traversing this we reach the outer or great Propylæum, with an outer and an inner portico, the forerunner in every essential particular of the great Propylæa at Athens, and of many others. Each portico takes the form of a distyle in antis, while the wall of the gate is pierced by a single opening in the centre, not between the jambs, but inside them, and their bronze-covered pivots worked in circular holes cut in the stone of the threshold, which was much wider than the wall. From the inner portico a door admits the visitor to a long, winding passage leading to the women's apartments, and just beyond the portico a short passage gives a side entrance to the court of the men's apartments. This Propylæum gives direct admission to a large outer court of irregular form; the buildings inclosing it to the south and west have been either largely obliterated by later buildings, or slipped down the hill with the line of fortification which gave way here. On the north side they are more perfect, and it is possible to trace distinctly the line of the small Propylæum giving access to the court of the men's apartments. This gateway was similar to the great Propylæum, having an outer and inner portico, and the gate-wall was provided with folding doors. The courtyard to which this gave admission was large, about 65ft. by 50ft. clear of the porticoes which surrounded it on three sides, the east, south, and west; this court was paved, and so also was the outer one, with concrete. Nearly in the centre of the south side was placed the great altar of Zeus, which is on the axial line of the vestibule which occupied the greater part of the north side of the court. The front of this vestibule took the form of a temple in antis, and was raised on two steps, forming a stylobate. The bases of the two columns and of the antæ remain; those below the ground level are of irregular form, but above

it are carefully squared to the line of the wall. This also is the usual treatment of the thresholds here, but at Mycenæ they are squared throughout. The bases of the antæ have their tops rebated and drilled with a series of holes for wooden dowels. In general the base stones at Tiryns are from 18in. to 2ft. high. The upper part of the anta was formed of timber beams placed in juxtaposition side by side, and dowelled to the base, and probably to each other; and these would carry the ends of the lintels, probably formed in a similar way of more than one piece, as was the case later with the great stone architraves of the Parthenon and other temples. The side walls of this vestibule were decorated with slabs of alabaster, richly carved and inlaid with glass. Three pairs of doors hung folding between the jambs gave access to an ante-chamber, from which an opening led to the Megaron, or principal men's apartment, which was over 30ft. wide and nearly 40ft. deep. In the centre are the bases for four wooden pillars which helped to carry the roof, and between them are traces of the large circular clay hearth found in much greater perfection in Mycenæ; the floor of the hall was of concrete, ornamented with a rectangular pattern in incised lines. The walls in the upper parts were of perishable materials—wood and sun-dried bricks—and these fell an easy prey to the fire which destroyed the Temple. From the ante-chamber access is also obtained to the bath-room, which could also be reached from the men's court. The floor of this room was formed by one single stone slab, sunk, polished and drilled with dowel holes for a wood lining to the room, and was provided with a movable terracotta bath and with a drain; this bath adjoins a long and winding corridor, out of which several rooms opened. It also led to the staircase to the middle fortress, and eventually to the women's apartments, and may have been intended for the use of servants or slaves. The women's apartments in general arrangement closely copy the men's, but they are smaller, and the two sets have no direct communication. The long passage from the inner portico of the great Propylæum gives access through a stoa on its west side to an open court; this communicated directly with the inner court of the women, which had stoa on its east and on part of its north side. The rest of the north side was occupied with the vestibule to the women's hall, and with the entrance to the corridor which ran round them. This court was drained into the channel from the bath already referred to, which was formed of rectangular terracotta channel pipes which fitted into each other. The south side of the vestibule is quite open, the span is about 18ft., and, therefore, a lintel would not require intermediate support. This vestibule is nearly square; east and west doors lead into the surrounding corridor, and on the north side a single door, about 5ft. 3in. wide, leads to the women's hall. This door is of special interest, for in the pivot-hole the great bronze pivot was actually found. In the centre of the hall there seems to have been a square hearth. East of this hall are several well-defined rooms grouped together, and only accessible from the surrounding corridor; they probably comprised the king and queen's sleeping-chamber, with a vestibule, while a small passage gives access to inner rooms, which formed the treasury and armoury; south of this passage is probably the position of the staircase leading to the roof. A few other rooms are accessible directly from the women's outer court, but their exact purport cannot be definitely fixed. The walls of these rooms stand for a height mostly of from 1ft. 6in. to 3ft., the lower portions being constructed of stone; above this height the walls seem to have been constructed of timber and sun-dried bricks, and were usually from 2ft. 6in. to 4ft. 6in. thick. Both the upper and lower parts of the walls, external as well as internal, were coated with clay and then lime plaster; the latter was painted in various colours, subjects being introduced as well as geometrical patterns. The antæ had usually solid stone bases, the upper parts being formed of massive timbers forming an end to the wall. It is probable that these timbers, and also the wooden columns of the porticoes and Megaron, were incased with bronze plates. The thresholds were, with one or two exceptions, of irregular form, but all, excepting a broad central band, which was carefully worked to the width of the wall and stood slightly above the finished floor-level, was worked down so as to allow the floor to be carried up to the wall-line evenly through-

out. The roofs were probably flat, formed of massive timbers, which carried reeds, and above them clay. There may have been an upper story over a good portion of it. This is one of the earliest Greek buildings of which we have any extensive remains, and belongs, probably, to the 6th century B.C., or possibly an earlier date even. It was finally destroyed in the early part of the 5th century, but the Mycenæ palace, which is of later rather than earlier construction, certainly cannot be later than the 8th century. We have thus a not incomplete idea of a palace of an early Greek king, and are able, in conjunction with the discoveries in the Mycenæ tombs, to form some idea of the splendour of their homes. They were essentially warriors, and there was little in the way of what we should consider luxury in their manner of living; but their fortresses and palaces were magnificently constructed, and the latter richly adorned, and their armour and weapons and utensils were often of precious material and most delicate and graceful workmanship. This palace possesses a genuine architectural interest, for in it we find evidence of the origin of much that we shall see in our study of the later marble architecture, and here already the difficulties of a trabeated system of architecture have been encountered and overcome. In the Megaron of the men, for instance, we have an arrangement almost exactly repeated in the Opisthodomus of the Parthenon. Here, too, we perceive the constructional *raison d'être* of the anta, which was repeated in the early stone and marble architecture, but which ceased to exist to have any real purpose, other than an artistic one, in those buildings which were entirely constructed of marble, and where this feature becomes purely ornamental. We detect, also, the fondness of the Greeks for colonnades or porticoes, a necessity, indeed, of the climate. The system of decorating walls with bronze plates may suggest an origin for the great friezes of later days. We notice, too, great facility in adapting the plan to the limits of the site and to its special requirements, and the importance they attached to a magnificent and stately approach to an important building. If we endeavour to realise the effect produced on a visitor to the palace in all its glory, we cannot imagine it to have been otherwise than a striking and grand one, for which the plan seems eminently adapted. The Propylæa at Athens is but an elaboration of the principle contained in the Propylæum at Tiryns, carried out on a magnificent scale and with the very finest materials and workmanship. Other examples may be found at Eleusis, Ægina, Epidaurus, &c., but none equalled in magnificence that at Athens. The older gateway of Kimon, of which remains exist, was on a more modest scale, and was partly built of limestone faced with marble slabs or stucco, and with marble antæ, and probably columns. The present building was commenced the year following that in which the Parthenon was dedicated, when mechanical skill and mathematical science had reached the utmost perfection, and was planned on a truly magnificent scale. The entire scheme was never carried out; the Peloponnesian War brought the work to a final standstill in 431 B.C., and at this time no portion of the building was finished, and much of it not commenced, or was up to foundation level only. The Propylæa itself consists of a massive marble wall, raised on a stylobate of five steps and pierced with five gateways; the line of the wall is approximately north and south, and to the west and east were two great hexastyle porticoes; the western one is very deep, and is flanked on either hand by less important porticoes with buildings behind. Somewhat similar but more extensive buildings were designed to flank the eastern portico, but were never carried out, though traces showing the starting and position of them remain. The site presented great difficulties—it was irregular, uneven, and with a very rapid fall to the west; but very skillfully were the difficulties turned to account, and admirably does the building fit its site. The portions that were actually erected, and which still remain more or less complete, comprise, briefly, the wall of the gateways; the east and west porticoes, both imperfect, the north-west wing, complete, except for the roof, and a small part of the south-west wing. A magnificent flight of steps, flanking the approach for chariots, must have led up from the entrance below the temple of Niké to the level of the western or outer portico, which stands

on a stylobate of four steps, but this approach no longer exists, and the steps now *in situ* are quite modern. The Doric portico, with a wide intercolumniation in the centre, was surrounded by a pediment, while the two lines of slenderer Ionic columns behind each supported an immense architrave in a single block, extending the full depth of the portico; the beam is partially hollowed out, to reduce its weight. The wall containing the gates, and which stood on a lofty stylobate of five steps, is pierced by five openings, which were originally filled with bronze doors; the central one (the largest) would be used by the Panathenaic procession; the two smallest side doors being of comparatively small dimensions. The side walls of this portico undoubtedly had low seats running their whole length, and this would form a magnificent and convenient place of meeting and discussion. The eastern, or inner, portico had a similar elevation to the western, but the columns were raised on a continuous square plinth or stylobate. The north-west chamber is fairly complete; its west wall stands on an earlier foundation in a different line, and to this the new work has been very cleverly adapted. This chamber is entirely inclosed by walls, the southern one being pierced with openings for a door and two windows, and having a portico of three columns further to the south. The doorway does not come centrally with an intercolumniation. The columns of this portico were also of the Doric order, but on a very much smaller scale than those of the great porticoes. The roof to this wing was hipped, and, as usual, flat in the pitch. The opposite wing to this was never completed, but there is sufficient to show the original design of this wing, which, while balancing the other in its total mass, differed widely in its plan, and no doubt in its uses. Even as a ruin the Propylæa produces an almost inconceivable effect of grandeur and magnificence. Turning round from the Niké bastion one comes full upon it from below, and one can realise the object of the deep portico on the west side, for nearly the whole of its richly-decorated soffit, when it still existed, would have appeared at once to an old Greek visiting it; while the great pediment of the central portico would have towered above the hipped roofs of the wings. The break in the roof-level, which on a section seems unsightly, would from no point have been visible, except at such a distance as to be unobjectionable. Finally, we will make a short inspection of the Eretheion, and though it is not the most typical temple to have selected, it is an interesting example of the Ionic order. When you have obtained some idea of the plan and elevations of the building, any of you who care to do so may examine for yourselves almost every detail of it. In the British Museum, between the Parthenon marbles and the new Phigaleian room, a great many fragments are collected together—an entire column, including cap and base, from the east portico, the only column missing from the exterior of the building, large portions of the architrave cornice, and various smaller details. One or two fragments from the Propylæa, including the cap, badly placed, however, and the drum of a column and part of an architrave, may be seen in the same room. Mr. J. Fergusson read a paper on this building before the Royal Institute of British Architects on February 14, 1876, but he confined his attention principally to the elucidation of the difficulties in connection with the arrangement of the interior. The exterior was divided internally, Mr. Fergusson showed, into two distinct temples; the eastern one at the higher level was dedicated to Eretheus, and the western, much lower, to Athene Polias, and this was the most sacred shrine on the whole Acropolis. This arrangement affects the exterior very largely. The position chosen for its erection is just at the point where the Acropolis rock commences to fall away rapidly. At the east end we find a hexastyle portico standing on a stylobate of three steps, with its architrave in position, and it would be complete but for the removal of the north-east column to the British Museum. Portions of the frieze of black marble also exist. The south wall remains throughout its whole length, but not to its full height. The stylobate and the base moulding of the antæ continue; and, as usual, the first course of stone is very much deeper than any of the others. At the west end of this wall is situated the caryatid portico, with six female figures; to this point a uniform level has been maintained, but this portico is founded on the stylobate of a large early temple, and below it there is a sudden

drop to the ground-level. The west façade had a blank wall for nearly half its height, with a plain central doorway; above this, the wall had attached columns, and was pierced with windows. The north wall extends far enough beyond the west wall to obtain a doorway in it entirely outside the building, giving access to a court lying to the west of a building, and entered from the great north portico; beside it is the principal doorway. This tetrastyle portico has six columns in all, and still retains part of its coffered ceiling; its floor level corresponds to that of the western doorway. The north wall is complete as regards its length. Sadly ruined as this building is, we are enabled to obtain a very fair idea of its general effect; from whatever point of view it is seen there is a charming variety of grouping and outline, and it is hardly possible to find a view in which at least two of the porticoes are not visible. Added to the beauty of outline, the delicate mouldings and the exquisite carving, which, though employed with no niggard hand, is concentrated on certain points, must have given the complete building an air of wonderful delicacy and refinement, and this was no doubt heightened by an extensive use of colour. We have now, said Mr. Smith in conclusion, considered more or less briefly each of the three buildings I proposed to describe to you. In the first case we had to confine our attention mainly to the plan, and observe its clever grouping and variety of line, with the early promise of future development. The other two examples belong to the very best period of Greek art, and as regards style, no more perfect examples of the Doric and Ionic orders are to be found, and it is interesting to contrast the two. In each case the materials and workmanship are the same, that is to say, literally the most perfect that it is possible to obtain. The Propylæa owes its impressiveness and dignity, which even in its present ruined state is undeniable, to the most careful grouping of the various parts, and its comparative massiveness, combined with the most accurate and carefully considered proportions of the relative parts and very delicate optical refinements. It is absolutely devoid of carving or sculpture, and there is no trace of such ever having existed; carving, indeed, was sparingly used in the Doric order, but sculpture was often used in a lavish way, as at the Parthenon; it was almost invariably set in some frame, such as the pediment or metope, and skillfully designed so that the grouping should give a contrast to the inclosing lines. In the Ionic order as typified by the Eretheion we find sculpture comparatively unimportant, though a sculptured frieze is by no means unusual; the carving of long lines of surfaces is, however, adopted; this is no doubt more suited to the slenderer proportion and more delicate effect of the composition.

Mr. HUGH STANNUS proposed a vote of thanks to Mr. Elsey Smith for his paper, remarking that he had made good use of his time and opportunities when in Greece. One interesting feature in the plan of Tiryns was that a foe must approach the stronghold with his right arm towards it, whereas he wore his shield on the left arm, showing how thoughtfully the Greeks designed their buildings. Owing to the great subtilty displayed in Greek buildings, the new points brought to light by recent discoveries needed careful consideration before they were discussed. The complex plan of the Eretheion was an admirable example of the elasticity of the Greek style, one which was remarkable also for picturesqueness of grouping and refinement of detail. Our works could not be Greek works. Temple said of the Early Christians, we must not do what they did, but as they did, and this might be applied to the Greeks and their buildings. Our works should be those of 19th-century England, racy of the soil and of the time.

Mr. H. O. CRESSWELL having seconded the vote of thanks, Mr. OWEN FLEMING said he should have liked to have heard more about the domestic buildings of the Greeks. The plan adopted by the Assyrians and Romans of providing separate apartments and even distinct buildings for the women did not seem to have been carried out by the Early Greeks.

Professor T. ROGER SMITH said the subject of Greek architecture was of great and increasing interest, because we were learning more of the thoroughness and completeness with which it was carried out. We neither wanted to build Greek works, nor could we if we did; but we could study them with advantage on account of the attention paid to proportion, detail, and grouping. Tiryns,

which was discovered a few years ago, was the first example we had of domestic Greek buildings, and it was interesting to see how completely the Greeks separated the men from the women. The men's portion was the most architectural, but was entirely cut off from the women's portion. The latter was approached by a door which opened on to a blank wall, rendering it impossible to get a view of the apartment. Another singular feature was that the buildings were surrounded by long and tortuous passages of approach.

Mr. F. R. FARROW supported the vote of thanks, which was carried by acclamation. Mr. ELSEY SMITH, in responding, remarked that, save at Sunium, hardly any white marble-work was to be found in Greece, and there the whiteness was dazzling. On much of the marble there yet remained a fascinating golden glow. Little was known of the domestic work of the Greeks until the palace of Tiryns was discovered.

#### DOULTON'S SANITARY APPLIANCES.

WE have received a revised catalogue of Messrs. Doulton and Co.'s "Sanitary Appliances," which contains many additions and improvements of special interest and value to the architect, surveyor, and borough engineer. One of the most important of these appliances is the "Tested Stoneware Drain-pipe," which is a selected pipe of the best London-made stoneware, each having been subjected to considerable hydraulic pressure. These selected or tested pipes have each the letter T marked upon them. To the builder and architect who are anxious to make the basements of their houses secure against the leakage of sewer-gas from imperfect stoneware pipes, which often contain flaws, or are porous, the tested drain-pipes will be a boon. Owing, in fact, to the imperfection of clay pipes, iron pipes have been used for under-house drainage in some cases, but only because of the uncertainty attaching to stoneware. Messrs. Doulton and Co., by testing each pipe and stamping it, have removed the doubt, and as stoneware is generally admitted by all sanitary authorities to be the most cleanly and incorrodible form of drain, there is little doubt that it will in future be employed. The testing of the pipes under pressure is the only way of detecting any flaws in the body of the ware. With "Doulton's Patent Self-Adjusting Joint" under-house drains can be rendered perfectly water and air-tight. This patent joint is so arranged between spigot and socket ends of pipes that any disturbance of the ground causing a settlement will not in the least affect the joint, which allows of movement without destroying the tightness of the joint. Doulton's Improved "Simplicitas Pedestal Wash-down Closet and Trap" is another improvement on the older forms of this type, combining a perfect trap, with cleanliness and elegance of form. The "Simplicitas" closet and trap are in one piece of stoneware, but made in various qualities in plain stoneware, white inside and brown outside, with ornamentation in colours. We consider this shape much superior to, and more pleasing than, the usual forms met with. The prices quoted range from £1 5s. to £2 3s. for the basin and trap, and with pine seat and two-gallon cistern, &c., from £3 to £14s. 6d.

The Lambeth patent pedestal "Combination" closets are illustrated by chromos, and show various designs, some of them ornamented with blue magnolia, wild rose, and other floral designs; the acanthus pattern decoration is handsome. We also note the Lambeth "Flush-out" closet—a very serviceable and cleanly basin, in which the whole force of water is utilised in flushing. The Improved Cottage closet is economical and strong, with Doulton's vacuum waste-preventer fixed over. The improved seats, with hinged flaps for pedestal closets, Doulton's improved flushing cisterns, and trough closets for schools and factories, their lavatories, automatic flush tanks, public sanitary conveniences, baths, and fittings, and a number of miscellaneous goods of constant requirement by architects and surveyors, are included in the new revised list. The development of this branch of the business has been so great that Messrs. Doulton and Co. have found it necessary to erect large additional works at Paisley.

The Holborn board of guardians have adopted plans by Messrs. Saxon Snell and Sons for the erection of additional buildings at Mitcham schools, at an estimated cost of £2,000.

## OUR LITHOGRAPHIC ILLUSTRATIONS.

## MOSQUE OF SULTAN AHMED, CONSTANTINOPLE.

MR. DAVID R. CLARK, M.A., of Glasgow, exhibited his beautiful photograph which we have reproduced to-day at the last exhibition in Pall Mall, held by the Photographic Society of Great Britain. The mosque is pure Turkish in its architecture, and not Moorish, of course. It is unique in one respect—that it has six minarets, which are very elegant and fine. The dome which surmounts the main structure is carried by four immense marble pillars, 3ft. in diameter (one of these shafts is seen at each edge of the photograph). The interior is decorated on the walls with fine *old* Persian ceramic and lustre tiles in greens and blues, brought by Sultan Ahmed from Persia for the decoration of his mosque which he built in 1610. The floor is covered with matting, as is the case in all Turkish mosques. There are splendid lamps in the interior, jewelled with emeralds and other precious stones. The small padella lights are hung at festival times from an iron grille suspended from the roof about 10ft. above the floor. The charming character of the gallery front, which is similar in its detail to that which goes round the exterior of the mosque, is specially worthy of notice. As may readily be understood, the taking of the photograph occasioned no small cost and trouble to Mr. Clark, who has copyrighted it. Fergusson, in his "Handbook of Architecture," gives a small view of this great building (woodcut 364). The Mosque in Citadel at Cairo is a reproduction on a somewhat smaller scale of the Mosque of Ahmed at Constantinople. Gautier gives a view of this latter original building. It is vaulted entirely in semi-domes, which support the central cupola. In front of it was a court, surrounded by a quadruple portico, comprised of columns with black-and-white capitals, and with bases of bronze. The main shafts which carry the dome, as already mentioned, have capitals carved in stalactites, and have at about middle height a plain broad band—about level with the springing of the secondary arches—covered with inscriptions in the Turkish character. The discussion as to the impiety and the sacrilegious pride of giving this mosque the same number of minarets as St. Kaaba or Holy Kaaba caused no little ill-feeling between the Sultan and the Imam of the latter mosque, who cried out against such innovations, and in consequence the works were interrupted, the Sultan not knowing what to do. He wished to place six minarets on his own mosque; but he could not erect them because that was the number of the minarets of St. Kaaba, which it was a sacrilege to rival. At length he fell on an ingenious plan to shut the Imam's mouth. He caused a seventh minaret to be built at Kaaba.

## CHURCH OF ST. IGNATIUS THE MARTYR, SUNDERLAND.

The church of St. Ignatius the Martyr was the gift of the late Bishop of Durham to the largest

parish in the diocese, that of Hendon, which forms part of the Borough of Sunderland, and was consecrated by the Bishop on the 2nd of last July. It is Early English in style, accommodating 750, is very severe outside, as the smoke of a large town and the nearness to the sea would soon affect elaborate work, so all the ornamentation has been reserved for the interior; but the exterior is a remarkably good piece of stonework, a fine hard sandstone from the Edmund Vyvers quarries, situated on the moors in the west of the county, being used. At present the church wants colour; but the eastern lancets are shortly to be filled with stained glass in memory of the Bishop, and it is expected that the decoration of the panelled roof will also be executed before long. The works were excellently carried out, at a cost of about £7,500, by Mr. J. Howe, contractor, of West Hartlepool, Mr. T. Carse being clerk of the works; and the whole building and its fittings being from the designs of Mr. C. Hodgson Fowler, F.S.A., of Durham.

## THE "FOX AND HOUNDS" PUBLIC-HOUSE, SYDENHAM.

THESE premises have been built at the corner of High-street and Wells-road, Sydenham, for Mr. E. W. White, and comprise extensive cellars in the basement, bars, billiard-room, with open roof and lantern, parlour, kitchen, offices, &c., on ground floor; club room and residence on first and second floors. The site of the present buildings was previously occupied by the stabling-yard, &c., attached to the old house, which stood back 25ft. from the frontage line in High-street and 60ft. from Wells-road. A "give-and-take" line of frontage was arranged with the County Council and the Lewisham Board of Works, whereby the public footway has been considerably improved at the corner and for some distance up the Wells-road. Externally the ground floor is in Portland stone and red bricks; the upper part in picked stocks, with red brick and stone dressings. The works were carried out by Messrs. Allen and Sons, of Kilburn; the partitions and fittings in the bar, which are in mahogany, were executed by Messrs. Buckley and Beach; the gas-fittings by Messrs. Vaughan and Brown; the pewtering by Mr. Banks—all from the designs and under the superintendence of Mr. T. H. Smith, architect, of 17 and 18, Basinghall-street.

## PETER JONES'S PREMISES, CHELSEA.

THE illustration shows recent additions to the Symons-street part of these premises. The tower contains the principal staircase to the domestic part of building, together with an Otis elevator to the kitchens on the top floors, which have been fitted up by Messrs. Slater, the engineers, with machinery for steam cooking. The works were executed by Messrs. J. W. Hobbs and Co., from the designs of Messrs. Perry and Reed.

## "BUILDING NEWS" DESIGNING CLUB: DESIGN FOR COUNTRY STABLES.

For description see p. 292.

A block of business premises are now in course of erection in Linthorpe-road, Middlesbrough, for Messrs. Carter and Co. The external facing is of Dunhouse stone. Each department of the work has been let off separately to the following contractors: Brick, stone, and plaster, Mr. J. Lord; carpenter and joiner, Mr. W. Thomson; slater, Mr. R. Mascal; plumber, &c., Mr. W. Lambert. The work is being carried out from the designs of R. Lofthouse, architect, Middlesbrough.

A meeting of the executive committee for the proposed restoration of St. Helen's Church, Bishops-gate, was held on Tuesday in Merchant Taylors' Hall for the purpose of considering the draft scheme of the Charity Commissioners as affecting the work. The rector submitted memoranda of structural repairs to the church from Mr. Ewan Christian's report and estimates prepared for the Charity Commissioners, showing that the total expenditure would amount to £4,092. A long discussion followed, in the course of which it was stated that a further sum, variously estimated at from £1,000 to £2,000, would be required. It was decided to take no further action until it was known what would be the amount voted by the Charity Commissioners.

The Bishop of Newcastle, six years ago, asked for a fund of £60,000 for promoting church extension in the populous districts of Tyneside, and for aiding in the restoration of churches throughout the diocese. A return just issued shows that the total sum raised for the object is £75,500.

## DANBURY CHURCH, ESSEX.

THIS sheet of measured drawings and picturesque sketches is contributed by Mr. Fredk. Oliphant, A.R.I.B.A., of Dover. The church, which is an extensive one, consists of a nave with aisles, a fine stone tower with five bells, and a lofty spire. The chancel has an aisle on the south side, and the sacristy is situated on the north. Parts are described as Norman, and Roman bricks appear; but the greater portion of the building is of 14th-century work, with later insertions; an ancient piscina, and the remains of sedilia exist in the chancel. The north aisle was partly rebuilt in 1776. In its south-east corner is a very long hagioscope, with a small niche beside it, and a square piscina below. The fabric has twice undergone the process of restoration during this century. In 1402 it was largely destroyed by lightning, by the devil's aid, or as was said, by a Minorite Friar or "insolentissime debacchans." In 1750, 20ft. of the spire was burned down. The modern store screen and font are admired by some and ignored by those who can see no beauty in anything new. The stall backs, poppy heads, and moulded bench rails furnish some good details for an architect's sketch-book, and the building is so charmingly situated on the top of Danbury Hill (the highest point in Essex, 700ft. above the sea level, midst lovely trees and quaint surroundings), as to form the subject of many an artist's picture. The tombs of the Crusaders inside the sanctuary, with effigies carved in oak, and dating from the 12th century, are associated with the St. Clere family, which anciently owned the parish. They repose within arched recesses, probably of 13th-century date in the aisles. On a clear day it is said St. Paul's Cathedral can be seen from Danbury Hill, which is about 30 miles from London, and five miles from Chelmsford.

## BOOKS RECEIVED.

*Lockwood's Builders' and Contractors' Price Book*, 1890 (Crosby Lockwood and Son), has been entirely remodelled and considerably enlarged under the editor, Mr. Francis T. W. Miller, A.R.I.B.A. In addition to the very complete price lists for each trade, which have been revised, and the useful memoranda and tables relating to each, and modes of measurement, the volume contains the principal provisions of the Acts relating to building and sanitary matters, the rules and regulations of the London County Council, the Corporation of London, headings for contracts, rules as to electric lighting, and numerous other data and tables. The volume has been reset in a new type, and the arrangement is clearer than in other books of the class.

## CHIPS.

The Corporation of Southampton have decided to erect covered swimming baths, Turkish baths, and private baths for both sexes, and at their last meeting unanimously adopted the design and scheme as prepared by Mr. W. B. G. Bennett, C.E., the borough surveyor, the estimated cost being £7,000. Contracts are to be asked for at once.

A new building is now being erected in Sun-bridge-road, Bradford, Yorkshire, in the Renaissance style. The architects are Messrs. Milnes and France; the builders Messrs. A. Broxup and Son, Bradford; and the stone-carving has been intrusted to Messrs. Howarth Bros., Stretford-road, Manchester.

The village of Otford has just been sewered and provided with a water supply. The works have been carried out from plans by Mr. Hennell, engineer to the Sevenoaks rural sanitary authority, Mr. W. S. Freeman, of Otford, having been the contractor.

The memorial to the late Bishop Lightfoot will take the form of a restoration of the Chapter-house of Durham Cathedral, and the erection of an effigy of the late Bishop in the Cathedral. The Chapter-house is one of the greatest of the Norman period in England. It was commenced by the first bishop and finished by the third; but was greatly injured by the works carried out in 1796. According to the report of Mr. C. Hodgson Fowler, F.S.A., the proposed restoration is estimated to cost about £5,000.

St. Andrew's Church, Dent, in the West Riding, was reopened on Saturday by the Bishop of Richmond, after complete restoration. St. Andrew's Church was erected in the 12th or 13th century. The total cost of the restoration has been £2,700. The architects were Messrs. Paley and Austin, Lancaster.

## WAYSIDE NOTES.

IT is to be hoped that the report which the Institute is to make on the subject of Building Legislation, will have some influence on the powers that be, and that are to be, concerned with any future revisions of existing laws, and the making of new ones. We have seen how the Manchester Society of Architects, greatly to their credit, have prevailed upon the corporation to include certain provisions in a draft Bill that will go far to improve the architectural aspect of that city; and surely if a provincial society can influence the authorities in a place like Manchester, the Royal Institute of British Architects could do much more to assist us in London. Times are ripe for making improvements in the present law with regard to building. There is a sort of undercurrent of feeling to be observed in the County Council that some attention should be paid to the matter over and above the mere patching up that is to be undertaken. Now, therefore, is the time for action. I am glad that the Institute is considering the question, and, through the medium of Mr. Slater, showing what has been done in the past, and what is to be expected of the future. And I hope that the committee who have the consideration of building legislation will not rest at mere opinion-giving, but take, or advise the Institute to take, really practical and energetic measures to assist in bringing to pass that model Building Act of which Mr. Slater spoke, and which is so much to be desired for both constructional and artistic reasons.

I hear that Mr. Slater's paper, which I have had the pleasure of perusing, was admirably read, and if somewhat long and detailed, the fault was on the right side. The bold hit at the abuses that have crept in the system of administration by district surveyors was a word well spoken and in time; consequently, as the old proverb says, "like apples of gold in a basket of silver." Good as we all admit the system to be, there is little doubt that the berth of a district surveyor is very often little more than a sinecure. "Get the surveyorship, and stick a clerk in an office at a hundred a year; do a little surveying, and don't forget to draw many fat fees," would appear to be the principle of working of some district surveyors. This is the grossest abuse of a good system—both good for the public and for the architectural profession. Doubtless the evil wrought in some quarters is counterbalanced by the devoted energy we find in others; but I would maintain that, where district surveyors are found to be merely *farming* the stewardship—for it does amount to *farming*, when all the duties are relegated to a clerk at a hundred a year—they should be relieved of the appointment, and the latter should be put up to fresh competition. The remedy for any defects of this nature should, as Mr. Slater hinted, when he said that the district surveyors should jealously guard against abuses, be in the hands of conscientious members of the fraternity. It should be their duty to keep recalcitrant officials up to their work, whenever they suspect that the latter are negligent, and seeking their own ends where they should be faithfully serving the public. I would urge this upon the body of district surveyors, because we know the antagonistic feeling there has been on the County Council with respect to the system of district surveying. Should such feeling at any time come to a head, it is difficult to say what might not be the upshot; and it would be an evil day when the district surveyorship were taken from the hands of private practitioners, and their duties relegated to an army of official overseers from the County Council's headquarters. Let those, then, who may be more particularly concerned in this matter be warned in time, and believe that Mr. Slater would not have spoken as he did on an unpleasant subject unless deeply impressed by hard facts that have come under his notice.

Architects will notice with regret the death of Lord Lamington, whose persevering endeavours to improve our public buildings deserved so much commendation in an assembly where, one may safely say, architecture is a dead letter. How often did Lord Lamington "call attention" to the state of buildings and institutions which, being the property of the nation, one might reasonably expect to see kept in a decent and slightly condition! But in spite of his late lordship's persistent efforts, things remain the same. There is the unsightly

"front" to the South Kensington Museum, and the "disgraceful" Exhibition sheds, even if the old complaint of the want of a permanent home for the National Portrait Gallery is now in a fair way to being removed. The thousand-and-one eyesores and negligences continue in the Metropolis, and the Burlington House Arcade stones continue to rot; add to this the blunders of past First Commissioners of Works in "improvement" schemes, and we may well-nigh despair of ever attaining our model Building Act that is to transform London from a city of deformities to a city of architectural gems. And now that poor Lord Lamington has gone, and his voice can no more be heard in the House loudly bewailing the things that be, the outlook will be, if anything, less cheerful. The hope for a "council of architecture" recedes still further into the mists of the future. Let not the reader imagine that I grieve over-much at Lord Lamington's decease. Following closely the course of Parliamentary discourse for the past few years, I have noticed how his lordship stood forth alone, time after time, in advocacy of architectural reform, now here, now there, in connection with public works of architecture in London. The very solitariness of this speaker's complaints brought them prominently forward as the only attempts in a vast assembly of men—of whom, it would be thought, some would plead for the rights of architecture—to amend certain matters that can only be regarded as public scandals. It is for this reason that I so much regret the death of Lord Lamington. His arguments may not always have evidenced profound knowledge of the subject; but they were always sincere, earnest, and well-intentioned, and as such have held my regard and respect.

According to a statement in Parliament on the 18th, part of the Newgate site is to be retained for prison purposes, and a part will be devoted to the Sessions House for the City of London, which has now been talked of for some time. This latter building, I suppose, will be erected by the Corporation, and by their architect the designs will be supplied, unless, indeed, they see fit to put the work out to competition, which would be more pleasing to us all.

I always hold that working drawings are unworthy the name if they oblige a workman to scratch his head in the comprehension thereof. I was thinking of your leader on "Working Drawings and their Interpretation" one day this week whilst observing a terracotta-setter at work on a job. The problem he had before him was a stringcourse or some sort of projecting moulding round an oriel window, which, on plan, had rounded edges. The thing looked simple and straightforward enough; but I opine that the working detail which he had on a board before him had been prepared by Mr. Blank when that worthy was a little over "on," by an architect of an unpractical turn of mind, or "fudged" by a lazy pupil. Anyhow, the drawing caused the terracotta-setter to scratch his head, not once, but several times, and, indeed, he had to call another setter, who also scratched his head a spell. Finally, I believe, the doubtful block of terracotta was shifted about the one-hundredth part of an inch; but this does not concern us here. The point is to impress upon draughtsmen the necessity for preparing real working drawings, such as the British workman can understand at a glance, and without the head-scratching, which I take to be the crucial test of the drawing's worth.

Scene in real life:—F.R.I.B.A., engaging new head-man, *log.*: "You know I want a real, smart draughtsman"—produces elevation designed by late (lamented) assistant—"a design like this requires a lot of fitting-in." (!)

I am glad that "A Young Builder" is interested in the system of building which I recently advocated, and I will do anything in my power to enlighten him further, though he will remember that I gave an *idea* that should be easier for men of his class to develop, each in his own way. The system is only desirable on large works—that is to say, unless clients can be found to pay the increased cost and obtain first-class work on small ones. My master-builder will take such a salary as his abilities command, give his whole time to the work, keep the builder's yard, the materials for which will be procured or hired at the expense of the client or building promoters,

and given up or sold at the conclusion of the works. In smaller works, where one man's time could not be filled unless he had several jobs on, arrangement might be entered into with the employers whereby the master-builder would receive a fair commission or salary, and supply materials, as in ordinary non-contract jobs. The main idea I would like to see developed is building under a system where architect, builder, and workman would be interested in the work, where the builder would be free of harassing care, and not absorbed in endeavours to make a low-priced contract pay, and where the workman may be valued for his worth, and not as an automaton capable of getting through so much meretricious work in a given time. Out of such a system true architecture would spring, and the Bankruptcy Court would have fewer builders' affairs to wind up. GOTH.

## THE BEGINNINGS OF GREEK ART.

THE third of a series of lectures on Pre-historic Civilisation and Greek Art, by Professor Boyd Dawkins and Canon Hicks, was delivered on Monday night at Owens College, Manchester, by Canon Hicks. The two previous lectures were given by Professor Dawkins—one on the civilisation of North-Western Europe in the prehistoric age, and the other on the prehistoric civilisation of the Mediterranean region and its relation to history. The third lecture was on the beginnings of Greek art. Canon Hicks spoke first of early pottery and other objects from the islands and shores of the Ægean, and of antiquities of the Hissarlik type. These were not Greek work; their date was not later than 1500 or 2000 B.C. Pottery of the Mycenaean type, the date of which was about 1200 B.C., was covered with free, flowing, and beautiful decoration. Passing, then, from the Bronze Age in Greek lands, he described the art of a people who knew the use of iron and who burned their dead. The pottery of this period was of a geometrical type—stiff, crabbed, and uninteresting. It was the beginning of Greek art. Who the makers were of the Mycenaean art he did not know, nor who brought in the geometrical art a little later. The abruptness of the transition suggested that they were conquerors. We were all anxious for more information which would show the connection between this art and the Homeric age, and enable us to wind up the controversy as to who were the primitive Greeks. The lecturer showed how Oriental influence came in like a flood upon the geometrical type of art, which he regarded as the beginning of Greek art, dealing in this connection with the early historic relations of Greece with Phœnicia and Egypt. Illustrations were given of the beginnings of Greek architecture, of early reliefs in stone or marble, the first attempts at sculpture in the round, and of other phases of art. The question was often asked, How far was Greek art original? The answer was that Greek art was original in its own inherent capacity, but not original in its patterns or designs. The Greek was original in that he had within him an abundant store of native genius. He was ready to accept suggestions from any and every hand—from Assyria, Phœnicia, Asia Minor, and Egypt. But when he received these suggestions he assimilated them. At first he imitated but very soon made distinctions. He improved on what he had. He combined, he readjusted, and out of the suggestions he received he constructed what was virtually a new art of his own. In the Oriental art there was a wild extravagance; there was a love in the Egyptian art of what was vast and overwhelming. But the Greek had a sense of beauty, a love of balanced perfection, a power of self-control and of self-restraint in art which enabled him to create an art which represented not only strength but grace, and which knew how to deny itself all those extravagant means of effect which were so fatal to much of the art of the Orientals.

A Masonic hall is about to be built at Dawlish at a cost of £650. The structure will comprise on the ground floor an entrance lobby, banqueting-room, tylers' room, and lavatories, with a staircase leading to the hall proper, on the first floor, which measures 33ft. by 22ft., and has an open timbered roof. The elevation is of Classic design, to be carried out in white Devon brick, with dressings of red Berkshire brick. Mr. G. Soudon Bridgman, of Torquay and Paignton, is the architect, and the contractor is Mr. W. J. Hatcher.

## "BUILDING NEWS" DESIGNING CLUB.

## A DETACHED STABLE.

THE drawings of the members of our Club for January are, generally speaking, very good indeed, and most of the contributors show, not only more care and industry, but an increased interest in their work, while we note in several cases that our previous criticisms and remarks have been attended to. The following is the text of our instructions for subject D:—A detached stable and coach-house, with residence for groom, suitable for erection in the grounds of a small country house. The stable to comprise two stalls and two loose-boxes, with a separate stall for pony or donkey. Coach-house for four vehicles. A harness-room adapted for use as a man's small day-room. A loft over stable and man's bedroom. Groom's dwelling to have living-room, small scullery and pantry, two bedrooms, and cupboard for store. Separate w.c. for house. Dung-pit and accommodation for men. Scale 8ft. to the inch. Sufficient drawings to show the design, including sketch; all on one sheet of paper to the size stated in conditions. Two elevations sufficient. Style of building left to the competitors.

"Fiddler" is, on the whole, the best, and "Skull and Cross Bones" ranks second. The third place is won by "North Star." We have had some little difficulty in making this selection, and although the merit of the designs, speaking broadly, is high and worthy of praise, it must be confessed that no one plan is eminently satisfactory. We have said much the same thing before; but it has to be occasionally repeated, otherwise some readers who possibly are very clever people, and at least able critics if nothing else, jump to the conclusion, in no way justified, that we suppose the selected plans are models of good planning, or even correct design. Such readers seldom take the trouble to read our detailed review of the designs, and always overlook the fact that we can only select the best design actually contributed. Had it been possible for gentlemen of this class to contribute, no doubt the result would have been far different. Only those who try to work out a problem know its difficulties, even in so simple a matter as that before us now. "Fiddler's" elevation seems to be very nicely designed, and would look suitable and unassuming, depending as it does on quiet effect and simplicity of detail. The stable plan is not an unusual one; but the doors placed thus make it very draughty, and the two central stalls are rather dark and in shadow. The pony-stall space is utilised as a passage-way, and the absence of a more correct rendering of this provision is almost enough to throw "Fiddler" out of the running. It would have done so but for other merits in the design found wanting in all the plans wherein the pony-stall was made much of. The loose boxes are very roomy, and the harness-room is well fitted for a man's day-room, as stipulated, and, placed where it is, becomes convenient for the stable-keeper to answer the call-bell. In this respect, too, the coachman's cottage is well contrived, making it easy for the wife to attend the bell during the absence of the men. The dwelling, too, is well divided off from the yard, without being isolated from it. The dung-pit and men's closet are situated in suitable positions, though a urinal ought to have been provided. The illustration given herewith shows the design fully. "Skull and Crossbones" adopts quite another type of arrangement, making his coach-house needlessly large. The stable is fairly good, but there are too many doors to it. The pony stall is dark, and the w.c. at the back of the manger is a very bad arrangement indeed. It certainly ought to have been outside, and there is no reason why the pony should be built in as here shown. The dung-pit is too small, and the coal-cellar is not well placed adjoining it. The elevations are designed with taste and drawn with ability, though the coarse way of showing the roof tiles is quite out of scale, and looks fidgety. The little perspective is prettily done. We reproduce the drawing among our plates to-day. "North Star" always works with neatness, and realises the importance of breadth and skyline in his compositions. In this respect we commend his design, and his plan is by no means a bad one. The coach-house is too large, and so is the yard. The washing-room is dark and unnecessary, with the other covered washing spaces outside. The stable is very good; but the harness-room is open to improvement, and the stairs—all winders—to the man's room

are little better than a ladder. The groom's or coachman's cottage is too much separated from the other buildings. "Dr. Jekyll" is an able contributor, whose work will improve as he grows out of being too ambitious, and avoids a straining after mere quaintness of effect. Americanisms are all very well, and if novelty be desired, they may be introduced in some cases with advantage; but English architects, at any rate in Domestic architecture, will find very little worth copying in similar work done by their Transatlantic brethren, in spite of all their dodges and cleverness. The absence of quietness shown by "Dr. Jekyll" is not so marked as these remarks would imply without qualification, and he draws nicely. The conical roof over the living-room bay is an expensive and overdone feature; while the simple lifting up of the roof ridge over the cottage part is meaningless and without any material advantage, while it would look most ineffective. If the upper rooms of the cottage required more height, the eaves and ridge all round might have been lifted up a foot or two. The w.c. out of the cottage porch is bad; the living-room would be most uncomfortable to sit in; the upstairs floor is badly planned, but the stable is a good one. "The Red Rover" is not up to his usual standard this time, and has drawn his design very carelessly. The coach-house is too big; the stable gains nothing by being placed up in the corner; the pony-stall is made into a separate stable; beyond which is the harness-room, with a further door leading out of the covered washing space for horses. At the end of this space the men's w.c. is placed, and next to it is the living-room window. The men's bedroom is reached from the loft, and is a wilderness of a place, with a door at one end and a fireplace at the other. "Ko Ko" has the merit of having secured a simplicity and suitability in his design which deserve praise; but it savours of the commonplace, and the entrance to the stable in corner is a mistake. The house is comfortable enough, and the stable in itself is well arranged, after the style of a plan we published not long since among our illustrations. "Pat" also locates his stable too much in the corner, and makes besides a further mistake in the size of his coach-house. In many points the design is a good one, and the group is effective in perspective. The w.c. out of the front porch only needs naming to show the sort of faults "Pat" can be guilty of. Over the arch outside a moulded brick string cuts right through the 9in. ring of cut brickwork forming the opening! The coach-house doors, too, are very ugly. "Cassowary" makes his stable L-shape on plan, so that the pony stall is round the corner. Too much is made of a washing-place, and the dung-pit is not well placed in front of the stable windows. The coach-house is too big. Externally the buildings leave little to find fault with, save the turret and the chimney tops—these are anything but good. "Cosmopolitan" enters his stable very awkwardly out of a square washing-shed, in which a restive horse might be very troublesome. The harness-room would be dark lighted out of this shed, and the house with one bedroom on the ground floor is not an attractive arrangement. The architectural treatment, though poor, is neither vulgar nor in bad taste. "Lord G." goes in for half-timber work, and somewhat overdoes it. The coach-house is too large, but the stable is rather conveniently planned. The cottage has a cramped look, and the dungpit is very badly situated. The drawings are nicely executed. "Wallaby" does not send a very original plan—we have somewhere seen one which must have been copied from it! The arrangements, however, are rather good, even if one does not want a loft as big as the coach-house devoted to pigeons. The external façades are pretty; we do not like the arched tile-hung canted sides to the first-floor bay carried over the square projecting window below; the window sashes to the bedroom must be far too high for anyone of ordinary stature to look out of them. "Coaly Tyne" overdoes his design, too much to please us quite, and the coach-house is much too big. The plan otherwise is a good one, and the drawings are crisp, careful, and clear. "Y" in a circle believes in the ornate, and he surpasses the last-named in this respect, culminating his effort in a "perfect terror" of a turret with side arched wings, a clock above, and a bell below in the centre. His plan has good points, and so for that matter have his elevations, but they are too florid and ambitious. This is a fault for which we also

must blame "A. G." in a circle, who works in a circular stair turret next the main gable, which inside only serves as a storeroom. There is so much to praise in the detail of this design that we are sorry to add our opinion about the plan, which is a very poor one. The delicate mouldings and plinth to the pilasters on either side of the archway to the yard would soon be knocked all to pieces by carriages going in and out. "Labor Omnia Vincit," with a little more care and less "dash," would have done a clever thing. His plan is spoiled by bringing in his vehicles round from the back of his coach-house, so that every time they are used an awkward turn has to be made. The stable is very good, and the elevations are pretty. The drawings are careless, and ought to have been better. "K. W. T." adopts the square-yard plan, and we praise him in general terms for his work, though we do not like his design. He draws very well, and we shall expect him to plan better. Fancy the men's urinal being placed directly in front of the living-room window, with the ash-heap by the side of it, and dung-pit beyond! The coal-place right before one on entering the house, under the staircase, is another example of "K. W. T.'s" want of care. "Jehu" is American or nothing. His perspective is clever; but the contrivance of the house, all for the sake of the central chimney-shaft, is abominable. Let "Jehu" look at the shape of his rooms. Imagine what a wretched place the living-room would be, the w.c. opening, too, out of the entry porch, and the scullery right on to the parlour fireplace. This contributor really is too good a man to be guilty of such folly. "Signum" sends a fairly promising plan grouped round a quadrangle, and forming a pretty composition from the outside; but he draws very indifferently, which is a pity. The sketch is also unsatisfactory. "Waverley" adopts a square plan for his stable, like "Fiddler," but lights it with windows down to about 3ft. above the floor, and these, be it noted, are out of the stalls and loose boxes! He has put a window in the end of his coach-house big enough for a studio or parochial school. His drawings are fairly good, and he ought not to make such mistakes. "So and So" draws better than he plans. Thus, his men's convenience and ash-place overlook the living-room, and the w.c. is off the staircase facing the front door. Half-timber is his style, and so is that of "McGinty," who should study rather better models. His perspective in bird's-eye is nicely executed. "Streona" is improving, and we are glad to place him higher than usual. He must still try to be more simple in the features he adopts. His clock turret is too clever by half, and the dog kennel at the base of it is childish. "St. Magnus" attempts a suitable style, and does so with some degree of success; but he sends no view. "Westward-ho" has an ugly-looking plan with one loose-box big enough for an elephant, and doors to the stable about wide enough for a goat to enter by. The loft has a pitch of 6ft. 3in. "Nox" is a capital draughtsman who pays considerable attention to detail, and although his elevations do not attain a high degree of merit, they show reserve and taste which ought to produce better things if he will go on and try again. We note his air inlets and all the rest of it. "Bunya" draws heavily and he does not plan nicely. His elevation would look passing well if built, but he hardly does himself justice. "Vyrnwy" clearly does try, and can sketch out a perspective. It was a pity to put it diagonally on the sheet, however. The design is too like a small model farm; but in many particulars we commend this member for his work, and wish we could place him higher. Space prevents our going too much into details here. "Salt Water" is another careful man, and he seems familiar with simple country buildings. The side of his house is very pretty, but the stable is commonplace. "Tyne" adopts a type of "Georgian" work, and if his plan was more satisfactory we would have placed him higher, for his drawing is capital. The house is much too ambitious, notwithstanding. "P. R. G." is a rather effective design, but drawn in a hard style, which does not improve it. "Cyclist" has two circular towers or turrets flanking the entrance gateway containing ugly staircases, and much too grand in idea. The other designs are thus grouped in order: "Glaucus," "Sarchedon," "Night Light," "Herbert," "Lycidas," "Cyclist" (second design, why not do one and do it better?), "Initium," "Country Bumpkin,"

"Horseshoe," "A" in a circle, "Mac," "Re-naissance," "Niger," "Pat" (Southport), "Fleur-de-lis," "Airedale," "Niblick," "Dot," "Dot Secundus," "Dono," "Mene-laüs," "West Anglian," "Coverac," "Icky," E. S. Wilson, Sunderland (nomotto), "Coombe," and "Reference."

#### ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE eighth ordinary meeting for the present session of the Institute took place on Monday evening: Mr. Arthur Cates, vice-president, occupying the chair, in the absence of Mr. Waterhouse, R.A., the President, who was, it was stated, suffering from influenza, and had gone to Spain.

#### BUILDING LEGISLATION.

A paper on this subject was read by Mr. JOHN SLATER, B.A., member of Council. The author said his topic was one of the greatest practical interest, and that as our great cities were getting greater and more populous year by year, so its importance also increased, although it seemed to be regarded with apathy by the general public. Having given statistics showing the enormous and rapid increase of the population of Greater London during the present century—which increase was almost paralleled in the manufacturing districts of Lancashire and Yorkshire—Mr. Slater asked whether the building regulations now in force, not only in the Metropolis, but also in the majority of our great cities, were suitable and sufficient for the necessities of the present day. He thought not; and considered that the Metropolis ought to have a Building Act which would be a model for other towns. For many years the Roman law, of which nearly all our laws were developments or modifications, referred only to landed property, and not to houses; but about 202 B.C. the population of Rome increased rapidly, and from that period dated laws relating to buildings, and (1) the institution of the party-wall, with its rights and obligations on the owners on each side thereof; (2) regulations as to carrying off rain-water; and (3) rights of light and prospect. Both in Roman and Byzantine regulations powers were found to control the height of buildings. The earliest regulations in the Metropolis were FitzAylwin's Assize of Buildings, passed in the first year of Richard I., exactly seven centuries ago, the general intention of which was very similar to that of the present Building Acts. These regulations were to be found in the Liber Albus of the City of London, compiled in 1419 by John Carpenter, the town clerk, during one of the mayoralties of Richard Whittington. Mr. Slater passed in review several London Building Acts, down to that of 1844, which, though manifestly imperfect, was in many of its provisions superior to the 1855 Act. (1) It provided a special court of appeal; (2) it placed the buildings, which were now entirely exempted from all superintendence, under special supervision; (3) the regulations as to carrying out work to any party structure were less likely to lead to dispute than in the existing Act; (4) it contained regulations as to drainage and as to width of streets, which certainly ought to be comprised in any Building Act; and (5) it contained better and more complete regulations as to footings of walls than the present Act or By-laws. There were at present no less than fourteen separate Acts in force in the Metropolis, while the County Council were promoting a Barking Creek Bill, containing other amendments affecting the general regulations of buildings. It was essential that all regulations as to streets and buildings should be codified and embodied in a single document, and that piecemeal legislation should cease. The Act should regulate the width, construction, sewerage, and gradient of all new streets, the line of frontage of the houses, and should provide for a sufficient number of adequate open spaces. It should define clearly the difference between public and private buildings; should exercise control over the situation and construction of the former, and the means of ingress and egress. To secure the prevention of fire, due stability and healthiness in all buildings, it should control the site; the construction of foundations, walls, floors, roofs, and chimneys; the drainage; the amount of space about a building; and the height of the building in connection with its position. It should provide an executive for carrying out its provisions, and a special court of appeal for all disputed matters. Regulations as to noxious

trades, infectious diseases, common lodging-houses, &c., should be relegated to a special sanitary code, as in New York. The author then referred to the foregoing points in detail. The present regulation as to the width of new streets—that they shall be at least 40ft. wide, including footpaths—was not sufficient; for a much-used thoroughfare there should be a carriage-way not less than 42ft. The definition of a public building should be as wide as possible, and none should be allowed to be erected with a frontage to one street only. Regulations should be made as to the construction of new streets, and there should be provisions made to secure a subway beneath it. The Manchester New Draft Bill contained many improvements, and he congratulated the Manchester Society of Architects upon the result of their representations to the corporation of that city. The restriction as to cubical contents was unnecessary as a hard and fast rule, and there ought to be a discretionary power of allowing larger buildings to be erected, if the authorities were satisfied with their construction. With the increased knowledge of the behaviour of stone and iron under heat, it was absolutely criminal to allow stone staircases carried on unprotected iron supports in buildings used as flats; and, in fact, all the provisions as to fire-resisting construction needed remodelling. The securing of due stability was an important point, but the most crying defect in the Building Acts was that the controlling officers had no power whatever over the materials used other than bricks and mortar. It would not be difficult to frame a schedule which would stipulate, for instance, that lead for gutters should not be of less than, say, five pounds per foot super.; that zinc should not be less than sixteen ounces, and the minimum dimensions of scantlings, &c. It was also time that some regulations as to the use of iron in buildings should be laid down—such as, for instance, the minimum depth of a girder spanning a certain opening. If such details were not to be provided for, then the superintending officials should be empowered to satisfy themselves as to the stability in each individual case, and be made responsible. As to drainage, the sanitary officers of the various vestries did their duty well; but a divided control was unwise, and the same officer should be responsible for both the erection of the building and its sanitation. Provisions should be made for underground rooms being to a certain extent protected from the damp, either by the walls being built in cement, or by forming a dry area. The close juxtaposition of the houses was a great evil in large cities, and a regulation prescribing a minimum distance between the backs of all houses, large or small, was most urgently needed. The existing provision was positively ridiculous, because it simply prescribed the area of the open space in the rear of a building. The minimum depth of that open space should depend on the height of the house, and should be at least equal to it. In the case of buildings facing public streets, the width of the street should govern the height of the house as a general rule, as in Paris, in nearly every city of the German Empire, and in Sweden. In the last-mentioned country streets 32ft. wide and less might have houses 43ft. high; up to 44ft., houses 54-56ft. high; and streets above 44ft. wide might have houses 66ft. high. Such stipulation was eminently reasonable; but power should be given to relax the rule in certain cases, provided the construction satisfied the controlling officer of the Building Department as to fire resistance, stability, &c. In order to avoid a monotonous skyline, a clause might be framed to the effect that if the front of a building be carried up as a gable, then the limit should apply not to the apex, but to half-way up the gable. The regulation of the relations between adjoining owners as to works to party structures needed reform, and the author suggested that under the definition of a "party-wall" in the Metropolitan Building Acts and its amendments, a mere fence wall between properties might be included, a suggestion which evoked a chorus of "No, No's" from the audience. The Building Act of 1844 had a wise provision, under which if the adjoining owner did not give his consent the matter was referred to the district surveyor, who was required to report on the matter to the court of appeal. With reference to light and air, a clause to the effect that a building owner should give notice of rebuilding to all parties who could be affected, and their surveyors empowered to

investigate the matter and to decide by a majority whether the building would injure anyone, and, if so, the compensation to be paid, or to absolutely veto the proposed rebuilding, would be an immense gain to a Building Act in a large city. Even with a liberally-conceived, comprehensive Building Act, well drawn and lucid in its provisions, disputes would certainly arise. To whom were these to be referred? The great desideratum was that machinery for enforcing the law should be simple, direct, efficient, and inexpensive, and that there should be uniformity of procedure. At present it was precisely the reverse; and a special tribunal should be created fit to deal with building disputes. Mr. Slater referred to a report of the late Mr. Justice Mellor and the late Mr. Joseph Gwilt, who recommended that a tribunal should be constituted, consisting of two persons, one belonging to the legal and one to the architectural profession; and he believed, if due care were exercised in the selection of the individuals, this would form a very strong court. Referring to the administration of a Building Act, he considered a body like the district surveyors should jealously guard against abuses; but there could be little doubt that abuses had crept in. If it were true that one district surveyor had held office for years after he was totally unable to climb a ladder, his duties being done, not by a totally authorised deputy, but by a clerk—if it were a fact that another found two hours a week sufficient for the personal administration of a large district, nineteen-twentieths of the work again being done by a clerk—it was a state of things certainly not contemplated by the framers of the Building Act, and it was no wonder that the office had fallen somewhat into disrepute in the eyes of the County Council. But the greatest defect was incidental to the Act itself; it did not allow the district surveyors to exercise the slightest discretion, or to take the least responsibility beyond seeing that the bare letter of the law was insisted upon. Many surveyors felt the absurdity of their position, and gave themselves a great deal of trouble, when they saw this insistence would inflict undoubted hardship, in order to minimise that hardship; but others would never budge an inch from the *littera scripta*. If the surveyors were armed with discretionary powers to be exercised on their own responsibility, they would always take care to have good reasons both for permissions and refusals; and such an alteration in the law would surely be welcome to all. In conclusion, Mr. Slater said the London County Council had not yet given due attention to the reform of the Building Acts; but he looked forward confidently to the day—in the not far-distant future—when this great Metropolis would be administered in accordance with the regulations of a model Building Act, and when London, in addition to being the largest, would be in a fair way to become the best arranged, best built, most sanitary, and generally most magnificent city in the world.

Mr. E. C. ROBINS, F.S.A., remarked that he sympathised with a good deal of what Mr. Slater had said in his admirable paper as to the desirability of constituting a tribunal before which building disputes could be brought. He was old enough to remember well the court of appeal which existed between 1844 and 1855 to which Mr. Slater had referred, and was engaged on three or four public buildings which came before the official referees, and distinctly recollected stout old Mr. Hoskins looking over the buildings. Difficulties arose even in the cases in which he was concerned as to the powers possessed by the registrar. He would, however, endorse the suggestion that some such authority ought to be reconstituted, but in a different form. We were getting out of scale in the height of our buildings, not because architects wished to make their structures more and more lofty, but because clients insisted on getting the most out of their land. The air-space to be provided behind buildings was, like the last matter, an important subject which required legislating on; the houses in Broadhurst-gardens and Fitzjohn's-walk, Finchley-road, were instances of lofty modern buildings which almost touched at the rear. There ought to be legislative powers to enforce the leaving of a clear space between a house and its own backwall; but he confessed he did not see how such a rule could be carried out in the Metropolis. In any amendment of the Building Act they must, he thought, go on broad principles, and not enter minutely into details; while

as to the various public health and sanitary measures, these ought to be consolidated into one Act, and all clauses now of a permissive character should be made imperative.

Mr. HENRY DAWSON thought there was an urgent necessity for immediate action being taken with reference to a proposed change of procedure by the London County Council. It had been announced at a meeting of that body that they did not propose in future to exercise any discretionary powers to waive the strict enforcement of Section 13 of the Building Act of 1855, by which it was provided that all recesses or openings in any external wall should not, when taken together, exceed one-half of the total area of that wall. It needed no argument to prove that to strictly enforce this rule would be very unjust and quite inconsistent with modern commercial requirements. In business premises in large towns it was absolutely essential that the openings in outside walls should exceed one-half the superficial area, and hitherto this had been permitted in the Metropolis. He, therefore, suggested that it behoved the Institute to petition the London County Council, or, failing their consent, Parliament itself should be applied to to compel the Council not to hamper business men in such a manner, and that openings be permitted to be made of any dimensions, so long as the superstructure was properly supported. So ridiculous a clause as No. 13 ought not to be rigorously enforced.

Mr. CHARLES FOWLER, F.S.A., proposed a vote of thanks to Mr. Slater for his very opportune and instructive paper. It was timely, for the London County Council were now seeking Parliamentary powers to amend their Building Acts, thus giving the Institute an opportunity to make representations as to those proposals. He thought they, as architects, were agreed that some limitations as to the height to which buildings should be allowed to be carried were desirable, although they would probably differ as to the extent of such restrictions. The London County Council already possessed certain powers as to heights of elevations in new streets; but these ought to be exercised with greater discretion than was shown by the late Metropolitan Board of Works, who allowed Northumberland-avenue to be so built up as to become a mere tunnel between high buildings. Mr. Slater seemed to think that the regulations under the Act of 1844 were better than those which now existed, in that they led to less litigation. He was not sufficiently old to remember much of the working of the Act of 1844, but judging from the regulations themselves, he should imagine the reverse was the case. A building disputes tribunal would seem to be exceedingly desirable if we could get it, and certainly it was notorious that the old system of referees was anything but satisfactory in its working. He did not think the plan suggested by Justice Mellor and Gwilt would work so well as Mr. Slater had supposed. It would be better if a legal man were appointed to weigh evidence and formulate decisions, he being assisted by two architects sitting as assessors. It was evident that if only a lawyer and architect sat together, it would be difficult for them to come to an agreement should they differ on any point. The subject of giving discretion to a board or to its officials was one of very great difficulty. He thought with Mr. Slater that if the discretionary power possessed by the London County Council were qualified by a necessity to give reasons for decisions, it would prove better in practice. The giving to a committee of a public body large discretionary powers would require to be very closely watched in operation. The Liverpool Building Act, which was revised by the late Sir William Tite, had several valuable features, particularly a rule as to the thickness of walls, which worked well, and ought to be introduced into any amendment of the Metropolitan Building Acts. Mr. Slater had passed a high compliment on the London district surveyors by proposing to intrust them with large discretionary powers; but, although it might not be approved by the public generally, it would be of enormous advantage to professional men practising in the Metropolis if the suggestion were adopted.

Professor KERR, in seconding the vote of thanks, referred to the District Surveyors' Association as a most useful organisation, forming a court of appeal in building disputes. Anyone who met with difficulties from one whom he regarded as an obnoxious district surveyor could bring his case before the Association, which

would give the matter every consideration. The Association tended to promote uniformity in the interpretation of Building Acts. He had personally always been in favour of the London County Council and its predecessor, the Metropolitan Board, usurping, if they did not actually possess, discretionary powers in dealing with the questions that arose as to operations under the Building Acts.

Mr. E. T. HALL moved the adjournment of the discussion, mentioning that the Standing Practices Committee of the Institute was now considering suggestions for the amendment of the Building Acts, and their report would be ready to be issued to members before the next meeting.

Professor ROGER SMITH seconded the adjournment of the meeting, and Mr. CARES stated that the next meeting, to be held on Monday, the 3rd prox., would be devoted to the adjourned discussion, and that in the mean time the Standing Practices Committee's report and Mr. Slater's paper should be printed in full and circulated among the members.

#### COMPETITIONS.

GOVAN.—The Govan District Lunacy Board met on Tuesday to consider the question of appointing an architect for the proposed new asylum at Hawkhead, when, after hearing a report on all the eight competitive plans by Mr. Sydney Mitchell, architect, Edinburgh, who had been appointed assessor to examine and report on the plans, the Board appointed the author of the plan having the motto "Concentration" as the architect of the new asylum, and awarded the first premium of £60 to the author of the plan having the motto "Modern," and the second premium of £40 to the author of the plan with the motto "Hawk." The other architects were awarded a premium of £20, in terms of conditions of competition. On opening the sealed envelopes containing the names of the competing architects it was found that the architect appointed to erect the asylum was Mr. Malcolm Stark, jun., 167, St. Vincent-street; the winner of the first premium, Mr. D. MacNaughton, 137, West Regent-street; and the winners of the second premium, Messrs. James Salmon and Son, 197, St. Vincent-street, all of Glasgow.

LEEDS.—TOWN HALL ALTERATIONS.—A meeting of the Buildings Sub-Committee of the Leeds Corporate Property Committee was held on Friday to consider the eight sets of plans sent in for the alterations proposed to be made in the internal arrangements of the Victoria Hall. The competing architects are Mr. Johnson and Mr. J. M. Brydon, of London; Messrs. E. Dixon and Co., of Oldham; and the following Leeds architects: Messrs. Chorley and Connon, Mr. W. H. Thorp, Mr. T. Howdill, Messrs. W. Hill and Son, and Mr. W. A. Hobson.

LEICESTER.—In a limited competition confined to local architects, the Newfoundpool School Board have adopted the design of Mr. W. M. Cowdell, of Leicester, for a new school to accommodate 500 children.

POLLOKSHIELDS.—The congregation of Trinity U.P. Church resolved some time ago to proceed with the erection of a new church, and after a limited competition the committee, being advised by an Edinburgh architect, selected the designs submitted by Mr. W. G. Rowan, architect, 234, West George-street, of the late firm of M'Kissack and Rowan, and have appointed him to carry out the work.

The third of the present series of six free lectures, given at Carpenters' Hall, London Wall, E.C., to members of the building trades, was delivered on Wednesday evening, when Professor W. H. Corfield, M.A., M.D., gave an extempore address on "Modern Sanitation," before a large and interested audience. Mr. H. J. Kennard occupied the chair.

The second cable tramway laid in Edinburgh was opened for use on Monday. The new line runs from Princes-street through Frederick-street, Howe-street, Royal-circus, Kerr-street, over Stockbridge, past the Academy grounds, and terminates at Comely Bank, adjoining the North public park. The line, which will be a great convenience to the people of Stockbridge—a district which will now be brought practically within the city—has been constructed from the designs and under the superintendence of Mr. W. Newby Colam, A.M.I.C.E., by Messrs. Dick, Kerr, and Co., of London and Kilmarnock, who have been represented by Mr. James More, C.E.

## Building Intelligence.

BARTON TURF, NORFOLK.—On Tuesday week this parish church, famous for the beautiful paintings on its ancient screens and other objects of archaeological interest, was reopened after restoration. The church was in a very ruinous and dilapidated state; there was scarcely a piece of the timber remaining under the old floor that could not be rubbed into powder between the fingers, and the buttresses and the walls on the north side were settling down badly, and have had to be underpinned. The work, which has been done by the contractors, Messrs. Cornish and Gaymer, of North Walsham, from the designs and under the superintendence of Mr. Arthur J. Lacey, will cost about £700. There still remain to be done urgent repairs to the tower, the restoration of the fine porch and large east window, which will probably cost a further sum of £350.

LOUGH RYNN CASTLE.—The important additions that for some years past have been in course of construction at the south and east end of this manor house, a residence standing picturesquely upon the shores of the lough in the midst of the Clements estate, are now drawing to a conclusion. The new portions are all of grey stone, quarried near Dromod, and the roofs are slated, the style being a freely-rendered Tudor Gothic. The new rooms are fitted up entirely with English oak that originally came from Her Majesty's dockyard at Devonport, in Plymouth. Colonel Clements' architect, under whom the whole of the extensive works have been carried out, is Mr. Thomas Drew, R.H.A., of 22, Clare-street, Dublin. The oak fittings in the downstairs rooms are all the work of Mr. Harry Hems, of Exeter. The new suite of rooms includes, on the ground floor, new vestibule and entrance, boudoir, and main saloon. The latter room measures 50ft. by 31ft., and is lofty in proportion. Its floor is of oak, and the walls around are wainscoted and panelled to a height of over 12ft.

#### ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

LIVERPOOL ARCHITECTURAL SOCIETY.—A paper on "Quantity Surveying," addressed to students, was read by Mr. H. L. Beckwith, F.S.I., before this society on Monday. Briefly sketching the origin of the quantity surveyor, Mr. Beckwith went on to define his duties, and showed how, in these days of competition and speed, it was most important that the quantities should be so described that the contractor, in running through the items, should have no difficulty in at once assigning a proper value to them. He also said he saw no objection to architects taking out their own quantities if they liked to do so. With regard to the liability of quantity surveyors, he remarked that he need not dwell on that point on this occasion, as the best way to prevent mistakes arising was to familiarise themselves with very little detail of their work. In conclusion, he remarked that he thought a great many more people would be induced to build houses for themselves if they could only satisfy themselves as to the original outlay not being exceeded, and a thorough knowledge of quantity surveying would help the architect very much in designing his building from a pecuniary point.

MANCHESTER ARCHITECTURAL ASSOCIATION.—The last ordinary meeting was held at the Diocesan Buildings on Tuesday, Mr. J. H. Woodhouse, president, in the chair. Mr. F. R. Farrow, A.R.I.B.A., read a paper on "The Ventilation of Public Buildings," which he treated in a most exhaustive manner. A vote of thanks proposed by Mr. Mould, seconded by Mr. Booth, and supported by Messrs. Hodgson, Stelfox, Hinde, and Willoughby, terminated the meeting.

A petition having been presented to the Local Government Board to issue a provisional order to empower the Cheadle and Gatley Local Board to acquire land in the Board's district for works of sewage purification and disposal, an inquiry was held at the offices of the Local Board at Cheadle by Mr. Arnold Taylor, one of the inspectors of the Local Government Board. There was no opposition to the scheme. The clerk stated that the Board proposed to acquire eight acres of ground near the river. The estimated cost of the scheme was £24,300.

## TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

## TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.). To India (via Brindisi), £1 10s. 4d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

## ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

## SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING for TWENTY-FOUR WORDS, and Sixpence for every eight words after. All Situation Advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page advertisements and alterations in serial advertisements must reach the office by Tuesday Morning to secure insertion.

## NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XLII, XLVI, XLIX, L, LI, LIII, LVI, and LVII may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—T. F. K.—T. W. H.—M. and M.—D. and B.—D. and E. G.—J. W.

MILLBROOK CHURCH COMPETITION. (We are unable to avail ourselves of the information volunteered in this matter, as sender has not authenticated same by any name or address.)

## Correspondence.

## IS NOT REGISTRATION DESIRABLE?

To the Editor of the BUILDING NEWS.

SIR,—Inclosed is an advertisement cut from a local paper. Perhaps its insertion in the BUILDING NEWS may tend to strengthen the cause of Registration.

21st January, 1890.

**BEGS** to thank the Public and Friends for the patronage bestowed on the Firm carried on for the last 15 years by **BEGS** to state that he is still carrying on the Business, and has made the Premises more suitable for all its Branches. Joiner and Builder, Architecture in all its Branches. Special attention to House Factorage and Valuation. FURNITURE of all kinds supplied, also a Good Stock of Dressers kept on hand. UNDERTAKING—Coffins of all kinds kept, also Hearse and Machine supplied reasonable. NOTE.—I am prepared to erect Buildings of all kinds, finished for a lump sum, and to give Probable Cost for Houses to be built, or Price for Old or New Buildings FREE of CHARGE.

—I am, &c., X.

SIR,—The following advertisements appeared in the Daily Telegraph on February 18th and 19th respectively:—

**IMPORTANT NOTICE.**—To Property Owners and others.—D. Vernon and Co., Auctioneers, Architects, and Surveyors, are prepared to include in their forthcoming SALE, at the Mart, Tokenhouse-yard, any eligible PROPERTY at fee from one guinea, including all expenses.—City Offices, 3, Ludgate-hill.

**HOUSES WANTED.** furnished or unfurnished. Good positions. Moderate rentals. D. VERNON and CO., Auctioneers, Architects, and Surveyors, have many clients still unsatisfied. Full particulars of genuine property sent to their City Offices will insure speedy Letting or Sale.—Address 3, Ludgate-hill.

—I am, &c., F. N. K.

## "QUEEN ANNE" REVIVAL IN LONDON.

SIR,—Your portraits of Contemporary British Architects are so good that no word of praise from me is needed, and the letterpress notes with the photographs are most interesting. It is stated, I notice, in the particulars furnished with reference to Mr. John J. Stevenson, in last Friday's BUILDING NEWS, that the Red House on Bayswater Hill, which he built for himself, was the first house in the so-called "Queen Anne" erected in London. Is this correct? If my memory serves me rightly, the house in Lincoln's Inn Fields, on the north side, near the Inns of Court Hotel, and the mansion just out of High-street, Kensington, not far from the Palace, were the first "Queen Anne" houses built during the "Free Classic" revival, and they were designed by Mr. Webb. It is well to state these matters correctly for future reference, hence my inquiry.—I am, &c.,

IMPURE RENAISSANCE.

## THE REBUILDING OF ST. CUTHBERT'S CHURCH, EDINBURGH.

SIR,—The time has now come when this strange chapter of architectural romance falls to be reviewed.

It is also fitting that the columns of the BUILDING NEWS, which were freely opened to the strictures passed upon it in October last, should contain these concluding animadversions, for it cannot be that such an occurrence in a city which boasts ascendancy in art and all things excellent, can escape the shafts of distant sharpshooters in due time.

By way of blunting the sharpness of their barbed points, I would say that, though the promoters of the present scheme are entitled to be saddled with the full responsibility of it, yet, as each of these gentlemen is but a part of the great system of church establishment, it is possible they may not have had altogether a free hand, as citizens, in the matter. This, at least, is a charitable assumption, as, otherwise, the appeals that have been made to them, formally and informally, would be comparable to those which "inspiration makes to unreason, rather than to reason." On the other hand, the fabled "coach-and-six" can always make short work of an Act of Parliament, if it has a mind to do so. Thus, Toryism and the Church by law established, and possibly even an Act of Parliament, may each have a share of responsibility in this matter. But there are others: the leading daily journal of our city, which poses as the enlightened champion of great causes, turned a deaf ear to the appeals made to it to save the city from the mistaken kindness of its friends; yet it could hug, in close editorial embrace, whole lengths of learned puerilities, and much innocent trifling besides (of a quality, for example, of the late Art Congress), while refusing to deign a glance at the foulness of its own ecclesiastical doorstep, and the unsavouriness of its own immediate surroundings. A band of enthusiasts also, in our city, has of late been clamorous for Home Rule for Scotland, who yet have failed to perceive this unarchitectural and unsanitary monstrosity in their midst; and, assuredly, they may set to work at once, for St. Cuthbert's Church is about to be transformed into a melancholy perpetuation of imbecility, and a great opportunity for the city is being lost, without a word or gesture of dissent or disapproval from them. Politics may be "a progressive science," and history "a progressive art," and there may be "a time to cast away stones"; but Toryism and the Established Church can, it seems, snugly nestle beneath the folds of an Act of Parliament, and, defying all sanitary and æsthetic considerations, and the claims of other citizens to be heard, comfortably say—"This is our rest, here will we stay, for we do like it well!"

It was satisfactory, however, to receive from the principal promoter of the scheme, recently, the following:—"I quite recognise the right of any public-spirited citizen to form and express his opinion in regard to the rebuilding of St. Cuthbert's Church." Such a privilege, conferred upon a citizen not of their ilk, was consoling; but, alas, when I ventured to press home the following simple inquiry—"Would you personally be willing to sink your own prepossessions, &c., in regard to the proposed rebuilding of St. Cuthbert's Church, if the public voice were to be adequately shown to desire it?"—no answer was vouchsafed to this moderate request. Yet herein lies the hope that this impending misfortune to

the city may yet be averted. It is but a hope, however, for in Scotland people "esteem their ministers very highly for their work's sake," and have not yet got beyond the pawky stage, even in Auld Reekie, when principles rather than persons, and measures rather than men, turn the scales.

The most that can now be done, therefore, in the way of mending matters, is to endeavour to state the case against the proposal in such a way that the promoters may be constrained (influenced yet, perhaps, by public opinion and the action of the city authorities) to make a holocaust of their present scheme, and yield up the site as a benefaction to the city. Here, surely, would be a magnificent opportunity for Religion to lay its offering upon the altar of Secularism, and be the better for it! Let any intelligent citizen also view the present structure from one of the city's western approaches, and, as he sees the upper half of it alone visible, and the under part hidden away as if in a pit, honestly declare whether £17,000 would be wisely or even sanely spent in giving a new lease of life to any building upon such a site, much more an ecclesiastical one. Let him next obtain a glimpse at the Caledonian Railway Station of the landscape-view, which would be Edinburgh's exclusive possession and delectation to all strangers entering the city there, if the present hulk were removed and did not obstruct it. Let him say whether ten such structures would be too great a sacrifice to make to secure it. Lastly, there would still be the double gain to the city of a new site, enriched with a more worthy edifice, and much more entitled, perhaps, to the appellation of a "National Zion."

Much has been heard of late from scientists of the importance, and even of the "indestructibility," of the atom. In political circles this is probably synonymous with the phrase, "One man, one vote." Scottish patriotism also demands in this matter that every citizen, irrespective of creed, should do his duty in making his voice heard upon it, or in endeavouring to influence others around him. Yet, should this proposal be actually carried out, it will be comparable to the act of a man who sets back his timepiece one hour, and refuses to be anything else than one hour behind "the correct time." Unfortunately for the city, this means being a century or more behind the age; unless, forsooth! a kind fate interposes, or something more than "church blasts of mimic thunder" are heard rattling round the new building before then.

I was just on the point of returning thanks, in anticipation, for giving publicity to these observations in your widely-circulated paper, when the postman handed in the following reply from the senior minister of St. Cuthbert's to the question I ventured to put:—"All I have any right to say in answer to yours, is, that if the public voice were adequately shown in the direction to which you refer, and adequately supported by the public pocket, it would receive, so far as I am concerned, very careful consideration."

I feel almost inclined to say here, "For what I have now received, I am truly thankful"; yet possibly the reverend doctor may, on consideration, make the terms easier, without going all the length of St. Paul, who made his benefaction "first to the Lord," and then to the recipient, "by the will of God."

AUDI ALTERAM PARTEM.

## THE WATER-CLOSET.

SIR,—As an old sanitarian with 30 years' experience, I have been amused, and sometimes almost provoked, to see the efforts of ingenuity bestowed upon this apparatus. The scientific plumbers and mechanicians combined have at last brought forth a machine which for complexity and liability to derangement, consequent repair, and subsequent bills for plumbers, beats everything I could have conceived.

I have before me a drawing of a w.c. which I will not name more specially than that it contains no less than ten distinct mechanical movements. It is, I think, as nearly complex as it can be; but perhaps some plumber with several, to me unknown, letters after his name will immortalise himself by adding another scientific crank or two—who knows? I know there are very many kinds of closets, but what I mainly write for is to protest, in the name of a long-suffering public who don't know what is really the thing, against this making a simple domestic appliance into a piece of clockwork.

I have put up perfectly good and working

closets at a cost of one-fourth of the general run of the advertised machines, and years of work have not caused half-a-crown's expense. I wonder that our architects and engineers do not protect the public from the gew-gaw apparatus which, if it goes on improving, will at last be good enough for a special lecture with diagrams in explanation of the working parts.

A water-closet with gauged quantity for each flush can be put up on the best, because most simple, principle, with all needful apparatus, for about thirty-five shillings, instead of a clock-work machine costing about four pounds.—I am, &c.,  
SANITARIAN.

## Intercommunication.

### QUESTIONS.

[10230.]—**Shutters.**—Towards the completion of a building it was found that the window-shutters which had been specified by the architect were entirely omitted in the bill of quantities by the surveyor. Does the owner have to pay extra for having them done, and can he get this extra cost from the architect or surveyor? Who is to blame?—CARELESS.

[10231.]—**Crematoria.**—Could any reader enlighten me as to the kind of furnace used for the cremation of the dead and how the process is conducted? Any information will be esteemed. Is there any work published bearing on the subject?—INQUIRER.

[10232.]—**Saline Stains in Wall.**—Can anyone give a certain remedy for the following?—Three years ago I restored a large country mansion situate close to the seaside. The new walls were plastered six months after being built with mortar composed of blown sand, ashes, and a mixture of fine, sharp gravel. According to specification, all old and new work was tied together with cement mixed in equal proportions with the same fine gravel. Wherever cement has been used the plaster has become stained and unfit to paint or paper. I am advised of numerous quack remedies to be applied on the outer walls. But what is to be done with, say, an 18in. inner brick wall, built in cement and showing both sides? If the saline matter is destroyed one side, I presume it will immediately eat out in another direction.—SALINE.

### REPLIES.

[10224.]—**Sound.**—No doubt an air space is a non-conductor to some extent. Sawdust is better, but objectionable on account of its tendency to harbour vermin. I have found, however, that the very best deadener of sound is a lin. thickness of silicate cotton (slag wool). It is also inexpensive.—C. A. GARDNER.

[10229.]—**Velocity and Volume of Flow in Sewers.**—Before the velocity of flow and the volume of discharge in a sewer can be calculated, the rate of inclination, or the length and fall of the sewer, must be given, together with the extent of the wetted perimeter and the sectional area of the waterway. Taking first the case of the egg-shaped sewer, 3ft. 9in. by 2ft. 6in., and assuming it to be a mile in length, having a fall of 6ft. in that distance, and to be running two-thirds full, also that the radius of its invert is one-fourth the transverse diameter—the first step will be to ascertain the sectional area of the waterway. This may be found by multiplying the square of the radius of the upper arch of sewer by 3.0232 (the area of a sewer of similar proportions, the radius of whose upper arch is unity), thus:  $1.25^2 \times 3.0232 = 4.72375$ . Of course, this might easily have been obtained by calculating from the known proportions of the given sewer the areas of the three sectors formed by the radii of the sides and invert of sewer, and deducting therefrom the area of the triangular portion of the side sectors. The length of the wetted perimeter would be also evolved in this latter operation. To obtain it otherwise, multiply the transverse diameter by 2.3941, thus,  $2.5 \times 2.3941 = 5.98525$ ft. Proceeding, then, by the following formula, which is Weisbach's reduced to the simple form of Eytelwein's, and is practically correct for the velocities usually met with in sewers—

$$v = 58 \sqrt{2Hr}$$

Where  $v$  = velocity in feet per minute;  $H$  = fall in feet per mile; and  $r$  = hydraulic mean depth or mean radius, or  $\frac{\text{area}}{\text{wetted perimeter}}$  in feet, and substituting the values in the data above, we have—

$$\begin{aligned} v &= 58 \sqrt{2 \times 6 \times .78923} \\ v &= 58 \times 3.07746 \\ v &= 178\text{ft. per minute.} \\ v &= 4.72375 \div .78923 \\ v &= 5.98525 \end{aligned}$$

The cubic feet discharged per minute is obtained by multiplying the velocity by the area, or  $178 \times 4.72375 = 840$ c.ft. The 12in. pipe sewer to be self-cleansing will require a greater fall than the preceding example. Let us assume that it has a fall of 20ft. in the mile length, and that it is running half-full. The hydraulic mean radius for a circular pipe, whether running full or half-full, is equal to one-fourth the diameter; the equation will therefore be—

$$\begin{aligned} v &= 58 \sqrt{2 \times 20 \times .25} \\ v &= 58 \times 3.16228 \\ v &= 183\text{ft. per minute.} \end{aligned}$$

$$\therefore Q = \frac{12 \times .7854}{2} \times 183 = 72\text{c.ft. per minute.}$$

—FREDERIC ELIE GAY, Bath.

The chair factories of Messrs. Hector and Inglis and Messrs. A. and A. Weir, in Berkeley-street, Glasgow, were destroyed by fire on Wednesday night, the damage amounting to £10,000.

### LEGAL INTELLIGENCE.

IN RE THOMAS QUINN, M.P.—A receiving order having been made on January 9 last against Mr. Thomas Quinn, builder and contractor, of the Estate Office, Popham-street, Islington, and M.P. for Kilkeny, the debtor has now furnished a statement of his affairs in which his liabilities are returned at £75,697, of which £9,097 only will probably rank, the amount of the assets being dependent mainly upon the realisation of various properties from which a surplus is anticipated. The debtor has been extensively engaged in the erection of workmen's dwellings in different parts of London.

### CHIPS.

Mr. Arnold Taylor, an inspector from the Local Government Board, held an inquiry at the Stockport Court-house on Friday, as to the application by the Town Council for a provisional order enabling that body to acquire from the Charity Commissioners 95 acres of land at Cheadle Heath for the purpose of a sewage farm, to carry out a number of street improvements, and to use land at Offerton Roughs for the reception of ashpit refuse. Much opposition was offered to the sewage farm and refuse-tip propositions.

The Improved Industrial Dwellings Company reported to their members, at the annual meeting on Tuesday, that of the forty-one estates belonging to them, all but two were in occupation. The houses were well filled, except those at the East-end, and the amount lost by defaulters in their rent was very small. The mortality among the tenants was very low—only 11 in the 1,000, as compared with the average of 17 throughout the Metropolis—and the birth-rate was high. When all the buildings are completed they will accommodate about 30,000 persons. A dividend of  $2\frac{1}{2}$  per cent. was declared for the half-year, making 5 per cent. for the year.

The prizes gained by the students of the Birmingham Municipal School of Art were distributed on Tuesday night, at the Midland Institute, by Mr. Thomas Armstrong, Director for Art of the Government Department of Science and Art. In a subsequent address, Mr. Armstrong defended the policy of the Science and Art Department, and said that what was wanted was an educated public opinion to insure that the advantages afforded by the Department were properly applied. But the future of art in this country in its application to manufactures depended upon a larger amount of time being given to it in the elementary schools, and in the thorough art education of those children of the wealthier classes who were destined to control manufacturing concerns.

From a return just presented to the Liverpool corporation, it appears that the cost of the Vyrnwy water supply scheme, now on the eve of completion, has been, up to December 1st last, £1,990,000.

The foundation stone of a Soldiers' Home was laid on Monday in the Edinburgh-road, opposite the barracks at Piershill, N.B. The building is being erected from plans by Mr. W. A. Carter, architect, of Edinburgh.

The contract for the erection of the second part of the new military stores at Forthside, Stirling, has been obtained by Messrs. James Hay and Son, contractors, Perth, by whom also the first portion was erected. The estimate is understood to be considerably over £30,000, and the work is expected to last for at least two years.

The York city council received a report at their last meeting, stating that the total cost of the restoration of the city walls (Bootham Bar to Monk Bar) had been £3,531, the original estimate for the work having been £3,500.

Mr. T. Stevens, of Bournemouth, has been appointed architect of a new Wesleyan Chapel about to be erected at Christchurch, Hants, on the site of an existing and smaller place of worship.

The parish church of St. Anthony in Menage, Cornwall, has been reopened after restoration. The contractors were Mr. C. H. Eva, Mr. Richards, and Messrs. Solomon and Co., all of Truro.

An action to recover compensation for damage done to a house by the fall of an adjoining building was tried on Saturday before Mr. Justice Charles and a Jury. The plaintiffs were Miss Ashley and Miss Shannon, living in Simpson-terrace, Victoria Dock-road, and the defendant, Mr. Simpson, was the owner of adjoining property, the point in dispute being whether the defendant had been negligent in the mode of repairing his houses. The jury awarded the plaintiffs £25 damages.

The old residence of the Grosvenors in Watergate-street, Chester, a well-known and picturesque feature in the Rows, having a half-timbered porch and magnificent staircase, has been purchased at £2,500, and will be converted into a city and county Liberal Club.

## Our Office Table.

THE London County Council are promoting a Bill this Session to enable them to introduce new supplies of water into the Metropolis, and to acquire the rights of existing water companies. The Bill, which is backed by Messrs. O. V. Morgan, Beaufey, Buxton, Causton, Cremer, Howell, Lawson, Montagu, Pickersgill, Rowlands, and Stuart, declares that the Council may purchase by agreement with any of the following companies:—The New River Company, East London Waterworks Company, Southwark and Vauxhall Waterworks Company, West Middlesex Waterworks Company, Lambeth Waterworks, Chelsea Waterworks, Grand Junction Waterworks, and Kent Waterworks, notwithstanding any enactment to the contrary, by a deed of conveyance. The Council are to have all the privileges of the companies, and be subject also to their obligations and liabilities, but will be freed from all the provisions of the special Act regulating the constitution, management, capital, and profits of such companies. Every officer and servant attached to any company at the time of the transfer shall, from and after the transfer, become an officer or servant to the Council, and shall hold his appointment upon the same terms as if the Bill had not been passed. The receipts for supplies are to be devoted to reducing the charge to the consumers, and also the metropolitan consolidated rate. The Bill, if passed, is to be cited as the London Waterworks Purchase Act.

THE sixty-fourth annual exhibition of the Royal Scottish Academy, opened on Monday, shows a praiseworthy effort on the part of the hanging committee, in obedience to public criticism, to raise the standard of the works admitted. The display is above the average, although the number of works hung has been reduced to 738, as compared with 1,032 in 1889. The space allotted to architecture and sculpture has been increased, and the latter is now shown in a room hung with pale green drapery. Of the 459 oil paintings, no fewer than 169 are sent in by members of the R.S.A.; but the President, Sir Noel Paton, and W. L. Lockhart do not exhibit this year. Millais is represented by his "Last Rose of Summer," a portrait of his daughter; Orchardson by "Deserted" and "Her First Dance," both examples of the spacious interiors in high life, with a graceful lady's figure, by which he has popularised his art. Flemish landscapes by Beattie Brown, Robert McGregor's "For the Crimea," Yorkshire scenery by Keeley Halswelle, portraits by J. L. Shannon, Thomas Graham (W. Q. Orchardson, R.A., being the subject), Martin Hardie, Burn Murdoch, and Hugh Cameron are among the oil pictures which attract the eye on a first visit.

"AN OLD EDINBURGH CONTRACT" was described in considerable detail by Mr. T. M. Rickman, F.S.A., in a paper read before the Institute of Builders on Thursday night, the 13th inst. The contract in question was that made and actually carried out for building the existing Exchange in Edinburgh in 1754, and the parties to it were the Dean and Guild of the city on the one part, and the mason, three wrights, and John Fergus, architect, all of Edinburgh, on the other, and the latter tendered to do the works for £19,707 16s. 4d., and to take the land forming the site off the hands of a city at £11,749 6s. 8d., making up a total sum of £31,457 3s. The tenderers, including the architect, seemed to undertake this as a speculation, and both architect and surveyors were apparently paid by the builders. The premises now on the site correspond, with singularly few variations, with the plan and elevation given with the contract, and in the minutest details named in the specification the works were evidently scrupulously carried out. The Exchange was, however, never used for its proper purpose, the merchants preferring to meet as of old at the Cross, and it was therefore sold by the corporation in apartments to a multitude of people, who are now the freeholders. The contract threw, Mr. Rickman showed, much light on the subject of building estimates and operations in Scotland 136 years ago.

THE distinguished Austrian architects, Messrs. Fellner and Helmer, have prepared plans for the "Mozart Festspielhaus," or Concert-hall, which is to be erected on a splendid site on the

Plateau of the Monchsberg at Salzburg. The building will form a sort of rival institution to the Wagner Theatre at Bayreuth, and the concert-hall is to be of unusually vast dimensions. It is intended for the performance of classical music during the summer months.

"THE NATIONAL GALLERY" was the subject of a lecture given by Dr. J. G. Fitch at the Working Men's College, Great Ormond-street, on Saturday evening. Mr. Frank Dicksee, R.A., presided. A visitor, said Dr. Fitch, could not get the full intellectual advantage which the Gallery was capable of rendering unless he examined the pictures with a clear and definite purpose. One special subject of interest was the history of religious beliefs as embodied in painting. The representation in fuller detail of the scenes of Sacred and Classical story came later, and was contemporaneous with the revival of an interest in Classical literature in Italy and in Germany. The serious, solid, and sincere, though somewhat prosaic, character of Dutch painting found in the Gallery was more fully represented than perhaps in any collection in Europe outside of the Low Countries; and the Peel collection and the Wynn-Ellis collection showed us at its best the power of Teniers, of De Hoogh, of Ostade, and of Mieris and Cuyp. In portraiture, also, our national collection was especially rich. A parallel was to be traced between the treatment of landscape by painters and the expression of a love of nature and her works in the literature of their contemporaries. A picture gallery was an epitome of history, and a record of the sweetest fancies, of the highest aspirations, and of the deepest religious convictions, of some of the most gifted men of past times. But it was also in a minor degree a test of character and of honesty; for there was always a temptation to be beguiled by great names or by the story of large prices into insincere admiration. Those who would guard themselves against this temptation, and endeavour by careful study to seek out the full meaning of any picture which they could honestly admire, would find at Trafalgar-square a mine of treasure, a store of new thoughts, and a source of genuine and innocent delight.

A report has been issued by Mr. F. Brady, chief engineer of the South-Eastern Railway and Channel Tunnel Companies, stating that the experimental boring carried on by the latter company near Dover has resulted in the discovery of coal, which first came to the surface mixed with clay, while a specimen of clean coal was taken at a depth of 1,183ft. 6in. The inhabitants of Dover, Folkestone, and Deal will not contemplate the creation of a Black Country on the south-eastern coast with feelings of unalloyed satisfaction.

At the last meeting of the Warwick Corporation it was reported that the works of water supply at Haseley had just been completed satisfactorily from plans by, and under the direction of, Mr. Richards, the borough engineer. The cost had been £1,100, exclusive of an honorarium of £55 to Mr. Richards, voted at that meeting.

In response to an appeal to the public by the council of the Yorkshire College for £40,000 to enable them to erect new buildings for the medical department, and also a college library and examination hall, more than half the required sum has been contributed. The council are prepared to devote £25,000 of the total sum to the buildings and equipment of the department of medicine, and £15,000 to the erection of the college library and hall.

A well-known buyer of English pictures has, it is stated, offered the whole of his fine collection to the nation on the condition that new rooms to hold it are added to the National Gallery within three years. If the offer is accepted it will be easy to carry out the conditions attached to it, for the space on which the new rooms would have to be built adjoins the site proposed for the new portrait gallery.

The fourth annual reunion of the Glasgow School of Art was held on Friday evening in the Corporation Galleries, Sauchiehall-street, when there was a large gathering of students and others. Mr. Lewis F. Day gave a lecture on "Art and Handicraft," after which a concert was given.

The corporation of Warrington have made terms with the local waterworks company for the taking over of their property on a basis of 30 years' purchase of the maximum dividends, the total capital liability being £267,569.

The local board of Hebburn has elected Mr. Humble, of Jarrow, as surveyor, in succession to Mr. West, resigned.

#### MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Society of Engineers. "Application of Water Pressure to Machine Tools and Appliances," by R. H. Tweddell. 7.30 p.m.  
Surveyors' Institution. "Establishment of a Tribunal for the Trial of Compensation Cases," by Sidney Woolf, Q.C. 8 p.m.

TUESDAY.—Institution of Civil Engineers. Discussion on "Waterworks at Shanghai, Hong-Kong, and Yokohama." 8 p.m.

WEDNESDAY.—Carpenters' Hall Free Lectures. "The Domestic Fireplace," by Prof. Armstrong, F.R.S. 8 p.m.

Society of Arts. "The English in Florida," by A. Montefiore. 8 p.m.  
The Ecclesiology of Denmark," by Major Heales, F.S.A. 7.30 p.m.

Society of Arts. "The Northern Shan States and the Burma-China Railway," by W. Sherriiff. 8 p.m.

FRIDAY.—Architectural Association. "Architecture in Oxfordshire," by W. A. Pite. 7.30 p.m.  
Royal Academy. "Florentine Sculpture in the Fourteenth and Fifteenth Centuries," by Prof. J. H. Middleton. 8 p.m.  
Royal Institution. "Evolution in Music," by Prof. C. H. H. Parry, Mus.Doc. 9 p.m.

Architectural Association, 9, Conduit-street, W.—February 28, paper on "Architecture in Oxfordshire," by W. A. Pite, Esq. 7.30 p.m.  
FRED. R. FARROW. } Hon. Secs.  
ERNEST S. GALE. }

#### BUILDERS' CLERKS' BENEVOLENT INSTITUTION.

The 23rd ANNUAL GENERAL MEETING of the donors and subscribers will be held at the offices, 21, New Bridge-street, E.C., on TUESDAY, March 4th, 1890, at 7.30 p.m. H. H. BARTLETT, Esq., President Elect, in the chair, to receive the Report and Balance Sheets for the past year, and elect officers for the present year.  
The TWELFTH ANNUAL DINNER will take place at the Holborn Restaurant on MONDAY, March 31st. Tickets, 6s. each.  
H. J. WHEATLEY, Secretary.

#### CHIPS.

The London County Council on Tuesday reversed its former decision, declining to assist in the widening of Green-street, Leicester-square, and decided to contribute three-fourths of the cost of the proposed improvement, after deducting the recoupment.

The new Board schools, Normanton, are warmed and ventilated throughout by means of Shorland's patent Manchester grates.

The local board of Widnes have passed a resolution asking their surveyor, Mr. Higginson, to resign his appointment.

A stone reredos is now in course of construction for St. John's Church, Canton, Cardiff, in memory of the late rector, from designs prepared by Messrs. Kempton and Fowler, architects, Llandaff.

The Mayor of Gateshead opened, on Friday, a new café in the High-street of that borough. Messrs. Stout and Dockwray, of South Shields, were the architects, and Mr. William White, of Heaton, was the builder of the premises.

At the last meeting of the Leamington town council, the health committee reported that they had directed the medical officer to supply a list of the houses in the borough which are considered to be unfit for human habitation. The recommendation was adopted *nem. con.*

A meeting of the York Architectural Association was held on Thursday evening, the 13th inst., when a lecture on "Legs and Wheels" was given by Mr. George Mosley.

In the Chancery Division, on Saturday, Mr. Justice Kay made an order granting a petition for the sanction of the Court to resolutions for the reduction of capital of the Hitchens Fireproof Plastering Company.

The Edinburgh joiners are agitating for an advance on their wages of ½d. per hour.

The foundation stone of a new Orange Hall for Limavady, co. Londonderry, was last week laid by the Hon. Mrs. McCausland, of Drenagh. Mr. R. Eccles Buchanan, C.E., of Londonderry, is the architect. The cost of the building is £600.

The Nuneaton Gas Company are about to extend their works, and have instructed Mr. J. S. Pickering, C.E., of Nuneaton, to prepare the necessary drawings and specifications for a new gas-holder 70ft. diameter and 20ft. deep.

A new church is about to be built at Blaengarw, and will be dedicated to St. James. Messrs. Bruton and Williams, Queen-street, Cardiff, are the architects.

Designs have been approved for decorating the chancel of the Church of St. Michael, Bournemouth, and the works are in progress, under the superintendence of Mr. R. G. Pinder, F.R.I.B.A.

Mr. James W. Szlumper, M.Inst.C.E., of Victoria-street, S.W., was in error referred to in a "chip" on p. 259 as the contractor for, instead of as the engineer of, the Barry Railway.

## Trade News.

### WAGES MOVEMENTS.

A COMBINATION OF BRICKMASTERS.—A meeting of Kent and Essex brickmasters has been held, and it has been decided to form a Union of the Medway and Thames brickmasters and flint merchants to protect the interests of the masters.

NORTH WALES SLATE TRADE.—At the March monthly letting of bargains in Lord Penrhyn's slate quarries full time will be worked. The output for many months has been restricted to five days. At the Llanberis quarries things continue very brisk. In the Nantlle Vale district, on the contrary, matters are flat. Three quarries are closed, and at a fourth work will cease after next settling day.

HOLLOWAY'S PILLS.—The Great Need.—The blood is the life, and on its purity depends our health, if not our existence. These pills thoroughly cleanse this vital fluid from all contaminations, and strengthen and invigorate the whole system, healthily stimulating sluggish organs, and establish order of circulation and secretion throughout every part of the body.

### DOULTING FREESTONE.

THE CHELYNCH STONE.—The Stone from these Quarries is known as the "Weather Bed," and is of a very crystalline nature, and undoubtedly one of the most durable Stones in England.

THE BRAMBLEDITCH STONE is of the same crystalline nature as the Chelynych Stone, but finer in texture and more suitable for fine moulded work.

Prices, and every information given, on application to CHARLES TRASK and SONS, Doulting, Shepton Mallet, Somerset. London Agent.—Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.

### HAM HILL STONE.

The attention of Architects is specially invited to the Durability and beautiful Colour of this material. Quarries Well Opened; Quick Despatch Guaranteed; Stonework Delivered and Fixed Complete. Samples and Estimates Free.

Address:—

THE HAM HILL STONE COMPANY,  
NORTON, STOKE-UNDER-HAM, SOMERSET.  
London Agent.—  
Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.C.

ESTIMATES GIVEN ON APPLICATION.

WM. OLIVER & SONS,  
MAHOGANY, WAINSCOT, WALNUT,  
TEAK, VENEER, and FANCYWOOD  
MERCHANTS,

120, BUNHILL ROW, LONDON, E.C.

The most extensive Stock of every kind of  
Wood in Planks and Boards, dry and fit for  
immediate use.

### TENDERS.

Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender: it adds to the value of the information.

BROMLEY.—For residence at Bromley, Kent, for the Rev. R. H. Lovell. Messrs. W. A. Williams and Hopton, 156, Regent-street, W., architects:—

Grubb ... ..	£1,675 0 0
Eccardt ... ..	1,473 0 0

**BROMLEY.**—For house at Bromley, Kent, for Mr. B. G. Gardner. Messrs. Wadmore, Wadmore and Mallett, 35, Great St. Helen's, E.C., architect:—  
 Crossley, Bromley ... £2,000 0 0  
 Arnold and Son, Bromley ... 2,079 0 0  
 Wiltshire, Sevenoaks ... 2,060 0 0  
 Jones, Tunbridge ... 1,985 0 0  
 Payne, D., Bromley ... 1,978 0 0  
 Grubb, Bromley ... 1,950 0 0  
 Holloway Bros., Battersea ... 1,893 0 0  
 Rooms, Clapton ... 1,850 0 0  
 Holt and Son, Croydon ... 1,850 0 0  
 Allen and Son, Kilburn ... 1,838 0 0

**BROMLEY.**—For additions to residences, Widmore-road, Bromley, Kent, for Mr. H. Mitchell. Messrs. W. A. Williams and Hopton, 156, Regent-street, W., and Bromley, Kent, architects:—  
 Lowe ... £494 0 0  
 Gregory ... 420 0 0  
 Rooms (accepted) ... 374 0 0

**BIRKENHEAD.**—For additions to house, Manor-hill, Birkenhead, for Mr. G. R. Clover. Mr. J. Clark, 19, Castle-street, Liverpool, architect:—  
 Bricklayer's and joiner's work:—  
 Hughes, T., and Son, Chester ... £1,400 0 0  
 Slatting and plastering:—  
 Johnson Bros., Liverpool ... 248 0 0  
 Plumbing, &c.:—  
 Catlow, B. and J., Liverpool ... 200 0 0  
 Gasfitting and bellhanging:—  
 Hamilton, R., and Son, Birkenhead ... 19 10 0  
 Concrete and oak-block flooring:—  
 Homan and Rodgers, Manchester.  
 Glazing:—  
 Williams and Watson, Liverpool.

**BIRMINGHAM.**—For house, Westfield-road, Edgbaston, for Mr. F. Wright, jun. Messrs. J. P. Sharp and Co., architects:—  
 Harley, J., and Son ... £1,585 0 0  
 Gill, G. ... 1,580 0 0  
 Gowing and Ingram ... 1,571 0 0  
 Whitehouse, B. ... 1,549 0 0  
 Goodman, J. ... 1,539 0 0  
 Webb, J. ... 1,489 0 0  
 Hughes, R. M. ... 1,441 0 0  
 Davies, F. ... 1,425 0 0  
 Giles, E. ... 1,378 0 0  
 Briley, F. J. ... 1,351 0 0  
 Jones and Mason, St. Mary-street, Ladywood, Birmingham\* ... 1,345 0 0  
 \* Accepted.

**BRIGHTON.**—For alterations and additions to No. 88, Preston-road, for Mr. G. H. Quin. Mr. E. J. Hamilton, Brighton, architect. No quantities:—  
 Barnes, J. ... £1,172 0 0  
 Lockyer, G. R. ... 1,170 0 0  
 Lynn, G., and Son ... 1,164 0 0  
 Cox, A., and Sons ... 1,088 0 0  
 Patching, and Son (accepted) ... 1,067 0 0

**BIRKENHEAD.**—For additions to house, 5, Cearn's-road, Birkenhead, for Mr. R. Marquis. Mr. J. Clarke, 19, Castle-street, Liverpool, architect:—

Bricklayer's and joiner's work:—  
 Lee, J., and Son (accepted) ... £226 0 0  
 Plumbing, &c.:—  
 Catlow (accepted) ... 48 10 0  
 Gasfitting, &c.:—Hamilton and Son.  
 Glazing:—Williams and Watson.  
 Concrete, &c.:—Johnson Bros., Liverpool.

**CAMDEN TOWN.**—For erecting shops, stables, &c., and executing various repairs at Nos. 13 and 20, High-street, for Mr. J. Bryan. Mr. R. J. Beale, A.R.I.B.A., Westminster, architect:—

Lamble, S. R., Kentish Town ... £1,067 0 0  
 Gould and Brand, Camden Town ... 1,019 0 0  
 Pryor, G., Walthamstow (accepted) ... 961 0 0

**CAMDEN TOWN.**—For erecting shop and executing various repairs at No. 80, High-street, for Mr. R. C. Widdicombe. Mr. R. J. Beale, A.R.I.B.A., Westminster, architect:—

Toms, E., Camden Town ... £339 0 0  
 Lambie, S. R., Kentish Town ... 332 0 0  
 Gould and Brand, Camden Town\* ... 319 0 0  
 \* Accepted.

**CAMDEN TOWN.**—For erecting shop and executing various repairs at No. 78, High-street, for Mr. H. James. Mr. R. J. Beale, A.R.I.B.A., Westminster, architect:—  
 Gould and Brand, Camden Town (accepted) ... £191 0 0

**CARMARTHEN.**—For alterations to the Carmarthen work-house, for the Board of Guardians. Mr. G. Morgan and Son, Carmarthen, architects:—  
 Jones, T., and Chapman, C. ... £1,141 15 6  
 Davies, W., and Thomas, T. ... 960 0 0  
 Jones, J. and D., Carmarthen\* ... 875 0 0  
 \* Accepted.

**CATFORD.**—For additions to Priory Cottage, Catford, for Mr. R. Archer. Mr. A. L. Guy, A.R.I.B.A., 78, High-street, Lewisham, architect:—  
 Laird ... £144 0 0  
 Jerrard, S. J. ... 121 0 0  
 Robson, Lewisham (accepted) ... 108 0 0

**CHRISTCHURCH, HANTS.**—For putting on a new roof over St. Michael's loft at the east end of the Priory Church:—  
 Howe, W. (accepted) about ... £1,000 0 0

**CLATTERBRIDGE.**—For two wards, &c., Infectious Hospital, Clatterbridge, Cheshire. Mr. J. Clarke, 19, Castle-street, Liverpool, architect to the board:—

Builder's work:—  
 Lee, J., and Son, Higher Bebbington (accepted) ... £1,898 11 9  
 For railing:—  
 Hill & Smith, Brierly Hill Ironworks ... 189 0 0  
 Concrete:—Homan and Rodgers.

**DAWLISH, DEVON.**—For building new banking premises at Dawlish, for the Devon and Cornwall Banking Company. Mr. G. S. Bridgman, of Torquay and Paignton, architect. Fittings not included:—

Stevens, C., Newton Abbott ... £2,156 0 0  
 Shapter, J., Dawlish ... 2,100 0 0  
 Stevens, H., Ashburton ... 2,090 0 0  
 Hatcher, W. J., Dawlish ... 2,040 0 0  
 Stacey, F. A., Newton Abbott ... 1,800 0 0  
 Webber, H., Paignton (accepted) ... 1,665 0 0

**DAWLISH, DEVON.**—For building a dwelling house, Brookdale-terrace, Dawlish, for Mr. J. Heam, solicitor. Mr. G. S. Bridgman, Torquay and Paignton, architect:—  
 Lamacraft, Dawlish ... £852 5 0  
 Hatcher, W. J. (accepted) ... 783 10 0

**DEVONPORT.**—For the erection of board schools at Morice Town, for the Devonport School Board. Mr. W. Curtis, architect. Quantities by Mr. T. Mullins, Plymouth, surveyor:—

Tozer and Son ... £4,040 0 0  
 Sanders, A. ... 4,030 0 0  
 Healy and Son, Devonport ... 3,524 0 0  
 Finch, J. ... 3,520 0 0  
 Jenkin and Son, Devonport ... 3,479 0 0  
 Roberts, S. ... 3,403 0 0  
 Lethbridge and Son ... 3,326 0 0  
 Laphorne and Goad ... 3,207 0 0  
 Pethick Bros. ... 3,140 0 0  
 Reed, J. ... 3,098 0 0  
 Blowey, P. ... 2,946 0 0  
 Debnam, A. R. ... 2,865 0 0

Rest of Plymouth.

**KENSINGTON.**—For the erection of a billiard-room, for Mr. F. Bailey, Addison-road, Kensington, W. Mr. F. Le Rossignol, F.S.L., 1, Gresham-buildings, Basinghall-street, E.C., architect and surveyor:—  
 Langham, J. (accepted) ... £649 0 0

**KILBURN.**—For rebuilding the Red Lion p.h., Kilburn, for Messrs. Warman and Co.; and alterations and additions to the Bon Marche, for Mr. W. Roper. Mr. W. T. Farthing, 46, Strand, architect:—

Bon Marche.	Red Lion.	Total.
Wall Bros. ... £4,297	£8,894	£13,191
Burman ... 4,177	8,350	12,527
Leslie and Co. ... 3,883	8,653	12,536
Holloway, H. L. ... 3,990	8,334	12,324
Scrivener ... 3,880	8,420	12,310
Godfrey ... 3,814	8,344	12,158
Shurmer ... 3,798	8,290	12,088
Baalam Bros ... 3,976	8,083	12,059
Spencer and Co. ... 3,684	8,183	11,867
Oldrey and Co. ... 3,767	7,990	11,757
Allen, J. ... 3,777	7,906	11,683
Todd, G. ... 3,690	7,889	11,579

**LIVERPOOL.**—For making up Mark-street, for the city council:—  
 Sterling and Swann (accepted) ... £284 0 0

# HAWKSLEY'S PATENT TREADS.

Proprietor & Manufacturer: J. WESTWOOD, Jun.

NAPIER YARD, MILLWALL, E.

Telegraphic Address—"Westwood," London. Telephone No. 5065.

Recommended for durability, simplicity, firm footing, elasticity, and are perfectly noiseless; they excel lead, oak, teak, or stone; applicable to wood and iron staircases, new and worn-down stone stairs, spiral and other staircases, footpath flaps to cellars, covers for drains and coal-cellars, flooring for public buildings and aisles of churches, &c., &c.—The best and most durable Tread or Step yet invented.

### ARCHITECTS' ESTIMATES.

TO arrive at any intelligent idea of cost a certain amount of knowledge is requisite. It not only becomes necessary to know the market value of materials, but the manner they are to be employed, in order that the labour expended in the work, whatever it may be, can be valued. Ideas of cost, nevertheless, are almost as varied and numerous as ideas of design: they can be often summoned for the occasion—spring up, Minerva-like, in the brain of the zealous bidder, or can be produced on the shortest notice by some rule-of-thumb method, but which idea may be as far from the truth as the merest guess. The all-believing public imagine it to be as easy to find the cost of a building as the cost of any everyday article; therefore the man who can give them at a moment's notice an idea of cost is the more likely to suit them, than he who retires to his office to take out rough quantities before he feels justified in submitting a fair estimate of any given building. The rough-and-ready guesser at estimates may now and then make a near hit, but the chances are against him: the actual fact being that he has omitted something, or overlooked the state of the market. Another class of estimators derive their knowledge second-hand: they obtain a quotation from a tradesman or manufacturer, which often is an overbid on the assumption that there will be no competition, and in this manner they become the dupes of designing firms who desire to obtain the work. Estimating by cubing implies a large experience and ample data; we do not deny that with these two necessities an estimate prepared by it may be a reliable guide, as it certainly is a valuable verification and a means of establishing a scale of comparative values.

An architect's estimate ought to avoid the two extremes of high and low pricing. It should be the result of an independent inquiry as to cost of materials of the required quality, and the lowest possible cost of conversion of material in labour and expenses, including a fair profit. He ought not to assume on the one hand the reputation of any builder who generally tenders above the normal price, nor should he, on the other, believe that he will have tenders from men who will be glad to work at cost price. Let those who tender send in prices based on one or the other of these suppositions, for such differences constitute the marketable advantage to be derived from open tendering; but the adviser has no right to base his calculations on these probabilities. From what we see and gather of competitions amongst builders, it is too plain that architects are inclined to make the surmises we have suggested above, and base their estimates on the knowledge they have of local builders who are likely to tender. In this manner their estimates are either high or low, and a really "protecting" estimate is impossible. We often wonder at the differences between tenders for works of a special kind, as, for example, a conservatory or an iron structure; but when the manner in which the tenders have been obtained are considered, an explanation of the disparity is obvious. A general specification of what is required, with a very inadequately prepared set of drawings, is furnished of the building, for which engineers are requested to send in an estimate. Nothing is specified, and no details are furnished. The contracting firms prepare their own details and specification, and send

in estimates which vary to a considerable amount. Firms of established reputation will send in a price allowing for the best materials and construction; others of less standing will use their tact in reducing the sizes and dimensions of the various members to what they think sufficient, regarding chiefly the object of obtaining the contract at any risk. Hence the difference of tenders. How much is left to the contractor in the design and execution is obvious; he can afford to underbid his more responsible competitor for the work some 30 or 40 per cent., and obtains the contract. A great deal of very uncertain and unsatisfactory contract work is carried out in this way. Horticultural buildings, heating apparatus, laundry work, iron construction of all kinds, hydraulic balance lifts, and engineers' work generally—all classes of work, in fact, a little more special than ordinary building—are left to the contractor. We cannot be surprised at inferior workmanship, for the system leaves the contractor his own master, while the credit or discredit of the work falls on the architect. To insure fair tendering and good workmanship, the architect ought to supply detailed drawings and specifications, leaving as little as possible that will admit of any doubt or difference of interpretation. In this manner only can a fairly-priced tender be received, as it requires each competitor only to take out the quantities and affix his own prices. Mr. Ironcaster doubtless objects to the completeness of a design in all details, with a specification that has been written by one who knows what ironwork is, as his chances of winning by sending in a low tender are gone. So long as he was not tied to sizes and sections, he could do as he pleased, and try to turn out a satisfactory job in the bargain. Thus, in a large iron structure a slight reduction of size or design in the section of a bar or rib may make a difference of some thousands of pounds. The speculative contractor likes drawings to a small scale, and finds it profitable to deal with architects who do not specify in detail or too minutely. Clearness and precision are his greatest enemies, for he can make nothing out of them; on the contrary, he rejoices when he finds a confiding architect whose plans are imperfectly digested or ambiguously described. The other class of manufacturer, if asked to give a tender, likes to be supplied with an accurate bill of quantities, or, at least, a set of drawings and specifications that are complete so that he may affix his rates. Many contractors we know refuse in short to tender for anything unless a responsible surveyor has prepared quantities and they are fully made aware of the requirements. The mixing up of the two businesses of tenderer and designer is neither congenial nor business-like. If tenders are wanted, they should be invited on facts duly stated and clearly expressed.

From what has been said, it is obvious that estimating is now left very much to contractors. We mean that the profession are satisfied to obtain quotations from builders and engineers for any required work upon insufficient data, or a very rough specification. An estimate is regarded as a sort of speculative thing, depending on the financial position of the tenderer. This sort of estimation has been due to the want of more care in the preparation of architects' specifications, and the practice of depending entirely on builders' tenders. There are two methods of preparing estimates: One is to calculate the probable cost to the builder by taking out the quantities and weights of materials, affixing to them their proper marketable values, and estimating the actual time and labour in workmanship; the other method is to lump the materials and labour in a given item. The workmanship or time is not given in detail; but each trade is priced at finished rates. Thus, flooring and roofing will be so many squares, or yards—of

flooring and timbers in the first case, and timbering, boarding, and slating in the latter. In estimating such an item as iron columns, it will be so many columns at such and such a length and diameter, with bases and heads so many cwt. at so much per cwt. The weights are finished weights. The first method dissects the work as much as possible, the other collects the various labours and items. Through the want of some system, young architects fail as estimators. A course of quantity-taking is of great service as an analytical process; but it will not be of much value to anyone till he learns how to combine the items, and is master of the value of labour and materials. We believe it is through the want of knowing how to price that so many architects depend on builders' tenders. After all, very little knowledge of the cost and marketable price of such things as a rod of brickwork, a cubic foot of stone or timber, a superficial foot of inch deal, or a cwt. of cast iron in columns, is necessary to enable the architect to check the amount of tenders he receives. The study of builders' prices to bills is of much value in obtaining data of this sort, and a good schedule is all that is necessary with a fair knowledge of measuring drawings. We have known rough estimates, but very reliable ones, made by simply taking a very few lump quantities—the round of the walls by their height, deducting large openings only, to allow for stacks; taking the "squares" of flooring and roofing, the framed doors per foot super., the sashes and frames per foot super., the staircases per foot, and numbering other items of less importance. But to do this kind of rough-and-ready estimating with a degree of accuracy, it is necessary only to be acquainted with a few analyses of prices. One should know, for example, how a rod of brickwork is made up; how many bricks are required; how much lime and sand, and the price of each, besides the amount of labour required in building. The item also of cartage has to be taken into account. So with timber. The prime cost at the yard, the sawing and cutting, must be ascertained before the price per foot cube can be ascertained. The price of deal can only be known intelligently when one knows the prime cost per C., as the rule is simple which takes a penny for every £10, and a halfpenny for every £5. Thus, if the prime cost is £45 a C., the cost per foot superficial of inch deal will be 4½d., adding or deducting 1d. per foot for every ¼ in. difference in thickness. This rule includes profit. Knowing the items which constitute the unit of price like the rod reduced in brickwork, and the price per foot-cube of stone or timber, is half the battle in estimating. If prices fail one, the recollection of the separate items in the price, as that of the cost of bricks per thousand, the price of labour and mortar in a rod, or the prime cost of timber, sawing, and carting, is enough to recall the price approximately to the mind. At least it is the analysis or dissection of the unit of measurement that enables the architect to better remember the prices. A mere arbitrary price, if not forgotten, is likely to be altered. Having the prices of the principal items of building at command, the difficulty of estimating is much reduced. The value of being able to estimate approximately one's own design is not small. More care is usually expended on the design; there is little left for speculation or doubt. We should not hear of the complaints of quantity surveyors, who find fault with imperfect drawings and specifications, for a man who could make his own estimate would be more exact in statement, plans and details would be more complete, nor should we hear of the enormous differences that now appear in tenders. The architects' estimate, if only a guide and a check, is useful. Instead of tendering being the last operation, as it ought to be, it too

frequently is resorted to as a tentative means of finding out what a certain design will cost to carry out, and to save a lot of trouble in preparing details and specifications—a means, in short, of eliciting practical information from tradesmen and others. No wonder that under such circumstances tenders and designs are ominously associated in the minds of the public.

#### GALLERY CONSTRUCTION.

EVERY now and then we hear of the sudden fall of church galleries. A recent occurrence of this kind has happened at a Congregational chapel at Bromley, which, unhappily, resulted in the serious injury of several of the congregation. The gallery appears to have been crowded, and during the delivery of the sermon it suddenly gave way. In the absence of particulars, it is impossible to surmise the cause of the catastrophe, though it must be attributed to some fault in the construction. Many of our town churches are still fitted up with these means of accommodating the congregation, and in not a few of them the galleries contain a very large proportion of the total number of worshippers. It becomes, therefore, very necessary that they should be equal to the greatest strain likely to be put upon them, not as merely expedients for overflow provision. Notwithstanding the risks to which people are exposed in buildings having galleries, there is little or no guarantee of their safety. The London County Council regulations apply to theatres and safety against fire; but no provision is to be found about the safety of galleries in churches and chapels. Surely this is a defect in the present law which ought to be remedied. It would be easy to require certain requirements of construction to be complied with—that the scantlings of the timbers should be of certain size for certain spans and projection, and that every gallery should be tested for certain maximum loads. In London the only reference to be found to the construction of church galleries is that of section 30, cap. 122, where it states that every public building (including in that term a church or other place of public worship) shall have its walls, roofs, floors, galleries, and staircases “constructed in such manner as may be approved by the district surveyor,” which means only that the plans and sections of the said structure are to be submitted for approval. No definite rules of scantlings or details of framing are laid down, and practically any section which looks strong enough is passed, the main thing being that the walls, floors, and staircases are in accordance with the provisions of the Act. Public buildings, forming a class by themselves, are exempted from the statutory clauses in force for dwellings and warehouses, and section 56 merely requires, in the case of buildings to which the rules of the Act are inapplicable, that the builder give notice and deposit plans and sections with the district surveyor. The construction, therefore, of a church gallery is left to the Board to approve of. As a matter of fact, the details have not to comply with any particular rules, as in the case of walls of dwellings and warehouses, or as in the case of theatres, in which not only the drawings, but a specification of the works, describing the materials and the mode of construction, are required as may be necessary to enable the Council and its officers to judge whether the requirements have been complied with. In the case of buildings for public resort it is required also that the accommodation in the different parts of the house or room the area assigned to each person, which shall not be less than 1ft. 8in. by 1ft. 6in. in the gallery, is to be stated. Nothing of this sort is demanded of churches or chapels; they may be crowded with people, and their galleries be packed far beyond the safe limit. Now what is required for theatre

galleries ought to be necessary for those of churches. The least area assigned to each person in a gallery should be stated. The above dimensions give a superficial area of 2ft. 6in.; but for a church gallery 3ft. would be a more reasonable limit. When a popular preacher fills a place of worship the chances are this area of 2ft. 6in. is even reduced. For instance, the galleries at Spurgeon's Tabernacle, we believe, often have their maximum load, and the same may be said of many theatre galleries, which, further, have to bear the stress due to applause. Being on an incline, the load is somewhat reduced in the proportion of the rise to the horizontal; but there is a circumstance which ought to be taken into consideration. In gallery construction the inclined beams which carry the floor are made to rest on the wall behind, and in front upon a girder supported by columns. It is material how these bearings are made. If the inclined beam only rest on a corbelling or a plate, there is an oblique stress as well as a horizontal thrust; the latter is in proportion to the cosine of angle of inclination. By the former there is a tendency to slide or slip out of the wall which a heavy load will increase. A beam in an inclined position is much weakened by the load upon it. In the ordinary gallery it will be found that the horizontal thrust is nearly equal to the load distributed. If we apply the rule, the general expression of which in words is: Multiply the weight in pounds by the cosine of angle and by the distance of centre of gravity from lower end of beam, and divide product by height of beam at the wall end from the horizontal; we shall find what little difference there is. In many a gallery failure the sliding or horizontal stress has been one cause of the weakness. If the main girder is liable to become deflected by the horizontal thrust, there is considerable risk in a crowded gallery. The chief way of obviating the sliding or horizontal thrust is to frame the inclined beams into tie beams, and make them trusses for the cross bearers, or to introduce iron ties to restrain the feet of the inclined beams. A thrust outwards would cause many cast-iron pillars to snap or yield, owing to the cross strain that would be brought on them. There is also the risk of the pillars themselves being insufficient to carry the load. We often see two spindling looking pillars of cast-iron supporting a gallery front of the whole width of chapel, perhaps 30 to 40ft. wide. Each pillar would thus have to carry a load distributed of from 10ft. to 13ft. by the half-depth of gallery; if we say the area supported on one pillar is 60ft., and take 120lb. on every square foot, then each pillar will have to sustain about 3 tons 4cwt. So long, therefore, as galleries are necessary in places of worship, certain restrictions and rules become important. The safe load on each square foot, or, what is the same thing, the minimum area per person; the angle of inclination of gallery—the steeper it is the more the necessity for precaution; proper trusses or ties, scantlings of timber, and adequate pillars, are essential points for consideration in the design of every gallery. These are points, moreover, which ought to be made the subject of building legislation. The construction of galleries and roofs are as important as the walls of a public building, and their design and execution should be carefully examined and supervised.

One of the duties thus involved would be the testing of the iron pillars and girders. Many of the failures of these structures have been owing to imperfect castings and execution. In some instances the girder rests unequally upon the thin cap or flanges of the column, or the load is taken on the outer edge of the cap, causing the pressure to exercise a cross stress, instead of being perfectly vertical. Cast hollow columns, if not very accurately fixed, so as to take the load

vertically, are doubtful means of support, on account of the unequal thickness of one part or a defect in the iron, faults which can only be discovered by testing under conditions exactly similar to those they will be required to fulfil in the building.

#### BRICKS AND BRICKMAKING MACHINERY.

By M. POWIS BALE, M.Inst.M.E.; A.M.Inst.C.E.  
Author of “Woodworking Machinery,” “A Handbook for Steam Users,” &c.

##### BRICK-CUTTING TABLES.

A VERY important point in connection with plastic brickmaking machinery is the cutting of the stream of clay into bricks after it has passed through the die of the moulding machine, and much ingenuity has been expended in this direction. The object to be attained is the cutting of the clay, whilst in motion, squarely across, so as to make an accurately-formed brick without wasting the clay or touching it with the hand. The plan almost universally pursued is to cut the clay by means of a series of vertical wires strained in a frame; these are either pulled through the clay, or the clay pushed through them, the bricks being delivered either at the side or end of the table. The inventor of the wire-cutting table in its improved form is Mr. Murray, of London, who introduced it some twenty-five years ago, and most of the tables now in use are based on this invention, although in America a series of knives attached to a fly-wheel or a number of revolving discs are sometimes used instead.

An improved form of brick-cutting table has been lately introduced by Messrs. John Whitehead and Co., of Preston, and this we illustrate by Fig. 8. The chief point claimed for it is, that the stream of clay as it comes on to the table is cut into the exact length required for a certain number of bricks without waste. This is effected as follows: The table is mounted on wheels, which run on two rails. The wires for cutting off the bricks are attached to a frame, which is rigidly connected with the carriage supporting the table. As the stream of clay issues from the die it eventually comes in contact with a vertical stop placed at the front end of the table, and pushes the table along the rails. The clay and the table then move at the same speed, and the stream of clay is divided squarely across into the length required for a certain number of bricks by a single wire at the rear of the table, actuated by a small lever placed under the hand of the attendant at the front end of the machine. The attendant now pulls the table towards him by the usual side-delivery action, which cuts the bricks, and deposits them on the boards without being handled. As the wires for cutting move with the table and the stream, the relative positions remain the same during the operation, thus securing a square cut. One of the supporting rollers, over which the stream of clay passes on its way to the table, is carried on a rocking lever, pivoted at its lower end, and as the gap which the clay has to bridge over increases, the supporting roller is shifted, so as to be always near the middle of the gap.

Our illustration, Fig. 9, represents an improved form of end-delivery brick-cutting table manufactured by Messrs. Clayton, Howlett, and Venables, of London. In this machine the table is worked by a lever action, and it is claimed for this arrangement that it is simple and better than a rack-and-pinion motion, and that the operator can cut and deliver the bricks on the barrow without moving his position. The bricks can be pushed forward on the board instead of lifted, and any thickness of bricks can be cut by a change of strain bars, which is readily effected. It can be used in conjunction with any kind of wire-cutting machine.

After the bricks or pipes are cut on the table, it is important that they are handled or shaken as little as possible, so as to avoid spoiling their shape. They are usually conveyed to the drying shed on bearing-off barrows, or trucks, or conveyor belts. If the former are used they should be mounted on springs, and wheeling plates should be laid down to insure a smooth road and avoid shaking. If boys are employed, trucks may often be used with advantage instead of barrows, as there is less danger of upsetting. In large works, where the semi-plastic process is in use, belt conveyors will effect a considerable

FIG. 8.

FIG. 9.

saving over hand-labour, as the clay is made into bricks always at one or more fixed points, and is sufficiently stiff to stand the journey by the conveyor to the drying shed or kilns without damage, and if the conveyors are well arranged very little handling will be necessary. In fields where hand-making is in vogue, and moulding is in operation at numerous points, they cannot be so readily applied.

#### DRAIN-PIPE AND TILE-MAKING MACHINES.

As the manufacture of roofing-tiles and small pipes is usually combined in one machine, we propose to notice them under one head. Owing to their thinness, to make good pipes and tiles, it is necessary that the clay should be of better quality than the ordinary brick clay, and more care taken in its preparation. It should be entirely free from stones, lime, and foreign substances, or the pipes, &c., will burst in the burning. The clay is usually prepared in the same fashion as for making ordinary plastic bricks; at after its passage through the pug-mill, it is screened and freed from stones, &c., by being forced through a perforated metallic plate. By fitting screens and altering the dies, small pipes or land drainage, &c., can be made by ordinary iron-cutting, brick-moulding machines; but for large pipes a special form of machine is necessary, and when a number of small pipes are required, a machine especially designed for pipe-making is to be preferred.

We illustrate herewith Fig. 10, a direct-acting steam-machine manufactured by Messrs. John Whitehead and Co., of Preston. It is especially adapted for the manufacture of socketed sanitary pipes. The chief novelty in the machine is Robinson's patent ventilating die, by means of which three pipes can be made at the same time. Fig. 10 gives an elevation of the machine and table; the top cylinder is a steam cylinder which operates a ram working in the bottom or clay cylinder. It has a metallic piston fitted with three steel rods, which are attached to the ram. The pipes as made are received by a rising and falling table placed immediately below the die at the bottom of the clay cylinder. The die is made of one solid piece of metal, and is without flaps; provision is made for the free flow of air to and from its interior. The clay cylinder is fitted with an expanding mouthpiece at the bottom, by means of which pipes of large diameters can be made. The dies for both small and large pipes are attached to this mouthpiece. Three pipes of the smaller sizes can be made at the same time.

Mr. W. Johnson, of Castleton Foundry, Leeds, constructs a horizontal machine (Julius Whitehead's Patent) for making large solid socket-pipes. The machine is self-contained, and fixed a little below the surface of the ground. The feeding and die part of the machine are on the same level, and immediately under the eye of the attendant. The clay is forced through the die by a steam cylinder and ram in the usual manner.

Messrs. Bradley and Craven, of Wakefield, manufacture a very simple and effective steam machine for the manufacture of large sanitary pipes. In this machine the steam acts directly in pressing the clay into and through the dies which form the socket and pipe, and the socket is made solid on the pipe at the same operation. The steam and clay cylinders are arranged vertically at the top and bottom respectively of an intermediate frame, which rests on supporting beams. The clay piston is attached to the steam piston by three rods, and forces the clay into the dies which form the socket and pipe, and are attached to the bottom of the clay cylinder. The steam-valve is operated by means of a hand-

FIG. 10.

lever, and another lever opens and closes the socketing. The method of working is as follows:—The ground clay is fed into the clay cylinder, and when this is filled the steam-valve is opened and the clay piston descends and presses the clay into the socketing die, which has been previously closed by means of the lever, and the socket and a portion of the pipe are formed, the exuding of a small stream of clay from an escape-hole indicating when the operation has been properly completed. The steam pressure is then taken off to allow of the socketing die being opened and the socket to pass out of it. Steam is again put on, and completes the pipe, which descends, socket first, on to a table beneath. The table is arranged to rise or fall as required, and regulates the length of the pipe being made. In addition to ordinary circular pipes, oval or egg-shaped pipes, ridge tiles, &c., can be made with equal facility.

For the manufacture of encaustic tiles various forms of pressure machines are employed, but we must defer our notice of them to another occasion.

#### THE SOCIETY OF ARCHITECTS.

AN ordinary meeting of the Society of Architects was held at St. James's Hall, Piccadilly, on Tuesday evening, Mr. E. Clerk Allam, vice-president, in the chair. The following members were announced to be duly elected by ballot: Anton Anselmus Andries, of Johannesburg, S.A.R.; William Joseph Jennings, Canterbury; and John Stalker, 31, Stramongate, Kendal.

#### THE PHYSIOLOGICAL BASIS OF THE SENSE OF BEAUTY OF FORM.

Mr. Albert Goodman read the following paper, which was illustrated by numerous diagrams, on this subject. Some may, the lecturer remarked, have a difficulty in abstracting the idea of form from that of colour. Turner's pictures especially excel by reason of their colouring. Yet a skilful engraver can entirely dispense with that element and still produce a copy of one of them which conveys many of the artistic merits of the

original. Apart from connection of ideas with regard to his subject and beauty of texture in his material, the sculptor has little besides beauty of form to depend upon. This connection of ideas is apt, more than we are aware of, to obscure many of our finer artistic feelings. To arrive at the correct estimate of the art-beauty of any form, we should choose some object that does not in our mind connect itself with the idea of an especial use or purpose. It is difficult entirely to fulfil this condition. Perhaps a beautiful vase is as good an object as any for practical experiment in analysing sensations as to beauty of form. A design intended solely for ornament would do still better, being in itself far more free from any connection of ideas of use. But an ornament bears relation to those surrounding forms and outlines, apart from which it would not have been designed; nor can it be considered properly or to such advantage when isolated. But in looking at any art-form the eye, and the eye alone, is concerned in transmitting to the brain, or producing in the mind, the consciousness of the particular form observed. The eye, like a machine, acts upon the art object which may be instructively thought of as the raw material, while the sensation of beauty may be regarded as the manufactured article. To vary the metaphor, the eye is the interpreter between the object and the mind, and he who would have his message properly conveyed must so arrange it as to be within the powers of the interpreter. To do this he must know the limit and range of those powers. In purely optical questions the eye is generally considered apart from the muscles which guide it, and is thought of as a system of lenses which project a picture upon the retina on the inner surface of the globe of the eye opposite the pupil. That the picture is there, and that some sort of an impression is conveyed to the mind by the mere fact of its being there, is not to be denied, but that any impression approaching in delicacy to an art-sensation can be produced while the eye is unmoved, is not to be believed; and such an idea is negated by the very structure of the retina itself, which shows that the continuous and varied use of the eye-muscles is a necessity for acute vision. Although like a globe in actual shape, the eye may be fitly likened to a photographic camera. The camera has compound lenses, so has the eye. Both have a focussing apparatus; the camera has a piece of ground glass at the back, and the eye has a retina to receive the image. On the ground glass the photographer rules some lines in pencil to show the limit of accurate definition, and the intersection of two diagonal ones indicates the point where he intends that the most important part of the picture shall be brought by the adjustment of the camera, and where he will place the sensitive plate to receive it. The retina of the eye has just such another point or spot, vision being there most acute. When any object is carefully examined or examined at all, or perhaps one may say even looked at or consciously noticed, the eye is so moved as to bring in succession upon the sensitive spot each part of the image of the object that is engaging the attention. These eye movements are produced by the eye-muscles and are instinctively performed. Impressions are conveyed without any muscular action to the brain by means of the optic nerve; these impressions are very vivid as regards colour and amount of light, but in the particular matter of appreciation of art-form, a retina rigidly fixed seems to have little or no power; indeed, the ordinary appreciation of form is not nearly so acute as we are apt to imagine. Until instantaneous photography came in, artists had failed, after generations of observation, to obtain a correct idea of the shape of a flash of lightning. For, although the effect through the optic nerve was most intense and lasting, such is the inconceivable shortness of the time that even the excessive rapidity of the eye-muscles could have no effect whatever in conveying an exact appreciation of the form by bringing the outline of the flash successively on to the sensitive spot. Now that we are familiar with these photographs, we can easily persuade ourselves that we can now see distinctly and correctly that which we failed to see in years gone by. We have then to consider how the muscles of the eye, like the arms of the photographer adjusting the camera, so move the globe of the eye as to cause each part of the image of the outline examined to pass over the sensitive spot. When a blind man endeavours to obtain an idea of the shape of an object, he moves his hands along its outlines

by means of the muscle of his arms. If the object were moved by another person so that it touched the blind man's hand, no impression of form would be conveyed to the blind man's brain. Now the image upon the retina of the eye is like a little model of the outline of the object, and this model is within reach of the sensitive spot; and the sensitive spot, like the hand of the blind man, is moved along the image by means of the eye-muscles. It is our purpose to consider the nature of these sensations of the eye-muscles. As a rule we use our two eyes in combination; but there is no reason to suppose that for artistic purposes a single eye would not be able to derive similar artistic pleasure from art-forms. Indeed, the flatness of pictures not being considered a drawback to them almost proves this. It will be best to consider the action of one eye alone, remembering that in whatever manner the muscles of one eye are moving, the corresponding ones of the other eye are moving in just the reverse way. Of the six muscles which move the eye, four are called the recti and the remaining two are called the oblique. The four recti consist of two pairs, and the two oblique are also a pair; thus making three pairs. The superior rectus pulls the eye so as to aim it upwards; thus in looking at a vertical line this muscle would move the eye upwards, and its pair, the inferior rectus, would pull it downwards, one resting, while the other worked. The external rectus moves the eye along horizontal lines, and its companion, the internal rectus, pulls it also horizontally in the reverse direction. The superior rectus and the inferior rectus may, for convenience sake, be called the vertical muscles, and the external and internal recti may be called the horizontal muscles. For working upon all oblique lines one horizontal muscle and one vertical muscle act in combination, and the same is true as respects all curved lines. Having made these broad statements, which lead up to the solution of salient problems connected with vision, certain corrections must be added which may enable us to solve some of the more recondite points connected with art sensations. It is not strictly true of all these muscles that each one acts in exact opposition to its companion. But, as with most muscles in other parts of the body, the vertical muscles slightly miss of this. Greater steadiness of movement in a joint results from the additional action of a third muscle, however weak it may be, provided that it pulls in a slightly different direction; just as a flag-staff is more steadily raised or lowered by three cords instead of two. The eye, although not a joint, moves in a socket, and is no exception to the rule we have mentioned. The oblique muscle seems primarily and almost entirely designed for steadying the eye during all the movements to which it is liable. As this goes on without intermission, and as this seems to be their especial function, we will not take account of them for our present purpose, except as regards one class of line—namely, vertical ones; these cannot be followed by a vertical muscle alone, but it calls in the assistance of one of the oblique muscles, which fact must be borne in mind, when examining the art-properties of perpendicular or nearly perpendicular lines. The knowledge of the peculiar action of these eye-muscles when used in observing straight and curved lines placed in certain positions with regard to the horizon will help us to account for some of the otherwise inexplicable phenomena of visual and artistic sense; why, for instance, the moon looks smaller when in the sky than when near the horizon; why a man, say 200ft. distant, on a tower appears far smaller than the same man standing at the same distance on the level road; why an oval is more pleasurable to look at than a circle; why a square held vertically appears higher than it is wide; why a square placed with its side obliquely to the horizon produces a different mental impression than that produced by the same figure placed in the first position; why certain arrangements of lines are visually delusive; why certain races of men have consistently for many ages preferred certain curves and arrangements of lines which find little favour with other races; why the individuals of every race have certain differences of taste from their relations and neighbours, although subject to exactly similar mental training. Little has been done to solve these points, except upon the lines that visual impressions as to form have some intimate relationship to the movements of the muscles which guide the eye. Of the fact that certain motions are pleasurable to the muscles

while other motions differing slightly are not pleasurable, we have many instances. Certain arrangements of muscles render certain motions enjoyable, while another arrangement renders those motions distasteful. When we wave our farewells to our friends, our hands move in ovals, not in circles. The grindstone and the treadmill for the man, and the mill for the horse, are proverbially unenjoyable. In short, all pleasurable muscular movements have a certain character, and all tedious movements possess another character. Change and variety, exercise and rest, are necessary for each individual muscle, if it is to be a source of pleasure to its owner. Even human eyes do not seem primarily constructed to produce artistic pleasure, but art adapts itself to the construction of the eye. But while art adapts itself to the eye, the eye trains itself to appreciate art. The trained eye of the artist can readily detect if an art object will give lasting pleasure to the ordinary man, or whether it will only give temporary pleasure. At a glance he can estimate that which the public takes a decade to experience. But the public is, for a time, pleased with anything which has a certain mixture of novelty from and resemblance to that which, just at that epoch, happens to be familiar to their eyes. Artists—and in that term I include all architects—have to appreciate this, and act accordingly. But architects especially should never forget that behind and above all this there is a right and wrong in art-forms, and that the public is really trusting to them to keep this standard in mind, and not to depart from it more than is needful. The stronger our belief that there is such a standard of right and wrong in art, the more we shall search for it, and the nearer we shall attain to it. Why should art be on a less assured footing than is music? And if the very natural question be put, "Of what practical use is a physiological theory as to the art-sensations of form?" it may be said, in reply, that this subject holds the same relationship to art as the science of air vibrations and the construction of the human ear does to music. The identification of certain rapidities of vibration with certain musical notes, and the responsive action of certain parts of the ear to those vibrations, may not directly help a great composer in the remotest degree. Yet music, being placed upon the assured foundation of scientific consistency, reaps an advantage from it in many other ways. Ruskin has from his own point of view felt the need of bringing art nearer to the fraternity of the more exact sciences; and that which masterly use of language can effect he has effected. Vague generalities have for ever been banished by his magic wand; and he has supplied thought far more exact and fruitful, and ideas which serve as great encouragements to the young artist, who delights to find that his own artistic instincts are in agreement with his great predecessors, and are consistent with immutable laws common to all ages. If, therefore, we can to any extent explain the mode in which sensations are produced in the brain when the eye falls upon an object of art, we shall go far to place art itself upon a more assured footing in the public estimation. Beyond this, we shall have a better means of properly estimating, at all events intellectually, the artistic merits of the art productions of other races of mankind. The practical application of these theories will be less tedious than the consideration of the theory itself. It is interesting to take certain art-forms and draw their outlines in colours or any other diagrammatic way which will show the especial muscles used as each part of the object is brought upon the sensitive spot of the retina of the eye. Let two colours, say red and yellow, represent the use of one of those two which we have termed the vertical muscles—namely, red for the superior rectus, and yellow for the inferior rectus. Let brown and green represent the use of the horizontal muscles—namely, brown for the external (say the right) rectus, and green for the internal rectus. Blue and black may be used for the superior and inferior oblique muscles. One eye alone, say the right, is taken into account; and that eye is supposed to be going round in a certain direction, say with the clock. First, take a square placed with its sides horizontally and vertically. This figure thus placed alternately employs a single muscle and then two in conjunction. The whole of the bottom line is green, showing that the internal rectus is alone employed upon that line. The left vertical line is

red, showing that the superior rectus does nearly all the work, the top line is brown, and the downward line yellow. Thus each of the four great muscles work apart from the other four—and every muscle rests three times as long as it works. The horizontal muscles work alone, but this they are the better able to do, being relatively strong. The vertical muscles are weak, but, receiving a little help from the oblique, they are thus slightly but not much more worked when looking at the square than are the horizontal muscles. That they are a little overworked is brought about by the fact that a square thus placed looks to be higher than it is wide. This may not be readily detected, but careful trial will prove it. Man's easy range of vision, even with one eye, is more extensive horizontally than vertically. Hence the outline of the majority of pictures, especially large ones, is greater in that direction: not that the four straight lines which inclose a picture are for the purpose of inducing the eye to travel over them continuously, but they inclose an area over all parts of which the eye may pleasantly range. In the light of these ideas we can well understand that a vertical line will be more apt to be objectionable when unduly prolonged than will a horizontal one. Hence a dado will be an improvement in a high room, but may be inappropriate to a low one, and a wall paper with vertical lines will be more suitable to a low than to a high room. Now place the same square with its sides at 45° with the vertical, and notice the great difference in its effect upon the mind. We hardly recognise it as the same figure. We now think of it as more resembling the diamond shape. Beginning at the bottom, the first line is an equal admixture of red and green, the next of red and brown, then brown and yellow, then yellow and green. In this case every muscle when working does half the work; and each muscle works half the time and rests half. The whole effect may be said to be fairly good artistically, certainly better than when the square is otherwise placed. Without the muscular explanation as to why the same figure produces a different mental impression when varied in its position relative to the vertical we should have been at a complete loss, as we have nothing analogous to this in purely mental operations. The colour representation of the muscular action when used upon the circular image projected by the sense of the eye upon the retina shows that each muscle gradually commences to act and stops equally gradually, and that no two muscles stop or start together; hence there is no particular point at which the eye can stop and reverse its action, or where it can easily glance off for the purpose of working upon other parts of the object, or the building, picture, or design, as the case may be. Hence there is no figure which tires the eye so much as does the circle. The circle is, however, an extremely useful figure when used as an ornament; for it, as it were, entraps the eye, and is thus able to divert it from other lines which are inartistic. When used for this purpose it should subtend a small angle, as in this case it is not nearly so wearisome to the eye as when the circle appears large; for it is not so much what the muscles have to do which fatigues them as the number of degrees through which they have to move the globe of the eye. Thus a circle should either be small, or only a portion of the whole 360° should be used. Hence the so-called Norman arch, whether stilted or otherwise, although consisting of as much as 180° of the circle, has an entirely different effect according to whether the arch is large or small relatively to the whole design. The oval, whichever way placed, presents, of course, somewhat the same features as the circle; with the exception that the relative proportion of rest and work of each muscle is different. It is, therefore, more pleasing as an ornament, but less forcible when so used, because the eye can leave it with more facility. It is, therefore, best used in close combination with other lines. But let us return to the circle, or rather the parts of the circle, for that curve is *par excellence* the one with which civilised architecture has to deal. The poor we have always with us, and also the compass and straight-edge. The civilised arts must ever chiefly avail themselves of such curves as the compass can produce. And in this necessity lies the great distinction, so far as art is concerned, between the architect and the artist of sculpture. However grand and beautiful may be the conceptions of the architect, only such of

them can be utilised as can be conveyed to another mind by means of straight lines, angles, and curves, which can be measured and reproduced by simple instruments. The compass is, therefore, the architect's necessity, and his endeavour should be to render it a useful slave rather than a tyrannical master. Mr. Goodman showed in detail and by references to examples how the particular curves and ornaments given to arches furnish the chief character of each style of architecture. Had there been no racial difference in art forms, the muscular theory would have been very one-sided and incomplete, however strong it might be against any other theory; but wherever a homogeneous race of men is found, there is also a distinct style of art. The gradual mixture of races, in some countries, confuses and obscures these differences of style. Conquered races generally receive an admixture of the blood of their conquerors, and hence cease to be homogeneous in their race and also in their art-forms, for the influence of the conquering race will be detected for an indefinite period after such an admixture. A closed and irregular figure, such as a vase, by the breaks in the line of any one colour, indicating the use of one muscle, better illustrates the successive and the proportionate work and rest of the muscles in a good art form than will the more geometric forms we have been considering. Any artistic picture, whether inclosed in four lines or otherwise, may in like manner be considered as a complex and interlocked system of outlines, so arranged by the artist that the eye of the observer is pleasantly exercised thereby, as, with inconceivable variety and rapidity, it travels in all directions, leaving no part of the picture unvisited. In a picture, although not coloured, gradations and alternations of light and shade take the place of outlines. But the addition of these new elements, and also the more complex one of colour, while they add to the intricacy of the subject, also add to its interest and importance. Although for our present purpose we speak of outlines only, and also speak of those outlines as though they were hard lines, yet a graduated shade, or the line of contact of two colours, is for our purpose virtually an outline, its attractive force to the eye being according to the difference between the two colourings or the abruptness of the change of shade. According to the same theory which we are considering, the principles of ornamentation are not far to seek. The general effect of any structure may be, or may not be, pleasing to the eye. If it be pleasing, it will require no ornament. If it be unpleasing, ornament becomes a necessity. But this is putting the matter in far too bald a manner when applied to an important work of art, such as a large building. And for this reason: the whole of such a building can never be seen at any one time; and every part will be looked at from a variety of distances. The influence of distance upon any line, as to the effect on the eye, is of great importance. Relative size of lines in art is self-evidently of supreme importance, as the whole thing depends upon that; but actual size, although all other parts are increased or decreased in the same proportion, is also of much consequence. It is an entirely different thing to the eye, whether it looks at a large circle or a small one, or, which comes to the same thing, whether the circle it looks at is near to or far off. A building, looked at from a certain distance, may require no decoration, but when viewed nearer may be ugly, unless that ugliness be corrected by decorative additions, or by slight or harmless modifications of the structure. When the eye is so close to a wall that no part of the structure of the wall is seen, the texture of the external substance of the wall acts as a decoration by giving the eye fit employment. On stepping farther back the texture is lost sight of, and at this point some structural lines, such as the joints of the stones, comes into view. But if texture is lost sight of before some such structural lines employ the eye, the wall must be decorated, and the size of the pattern of this decoration must be such as to employ the retreating eye until the observer can catch sight of some structure or ornament. Thus the wall-paper of a large room must have a larger pattern (supposing panels or dados, &c., are not used) than one employed for a small room. But let us imagine the observer to be so far away that some portion of the structure does catch his eye: at this point all texture and small decoration lose significance, and ornament may be needed—but

only in case of the lines of the structure then in sight not happening to be such as would please the eye. In that case an ornament becomes needful; but this must not be such as will arrest the eye when the eye is at such a distance as to allow of a more comprehensive view of the whole structure. To sum the matter up in a sentence: When the form of any structure is not pleasing to the eye, that is an evil which should be remedied as far as possible by ornament; but if the remedy does not cease to have visual effect at the distance at which the evil is lost sight of, then such ornament becomes an evil, and the remedy may prove worse than the disease. I have endeavoured to place the whole subject before you in its broad and comprehensive form. Hence I have not attempted extreme exactness in anatomically describing the combined action of all the six eye muscles. But you will find that the differences between anatomists as to these matters leave our theory unaffected. And had we still further simplified the matter by only taking into consideration one of the horizontal muscles, together with one of the vertical or even the superior oblique and the external rectus, and examined the effects upon those alone, most of the points we have noticed would have been brought out nearly, if not quite as well. I cannot now deal with the more fascinating part of my subject, which consists in the application of the muscular theory to details of ornament, such as to the exact sizes of circles, to the proportions of ellipses, spirals, quick and slow curves combined, contrasted curves, zigzags, angles acute and obtuse, checkered work, the inclination of roofs and spires, &c.

At the close, Mr. W. H. SETH-SMITH, ex-president, proposed a vote of thanks to Mr. Goodman, which was seconded by Mr. H. ROUMIEU GOUGH, past-president, and supported by Messrs. S. C. JOHNS and W. ALLPORT, and the Rev. S. O'BRYEN.

#### BOOKS RECEIVED.

*Laxton's Builders' Price Book* for 1890, seventy-third edition (London: Kelly and Co.), is well up to date, the prices show no tendency to fall, and advancing rates in several trades are anticipated. The new edition is noticeable for the attention paid to specialities in every branch. Electric lighting, sanitary inventions, new decorative materials, improved locks, machine-made joinery, American and Stockholm goods, wood-working machines, and a variety of other developments of building industries are treated and the prices quoted. Some useful advice is given upon sanitary work, though, of course, on matters of this kind opinions will differ. Reference is made to the upward tendency in the iron market; and the volume contains the usual notes and decisions of cases bearing on the Metropolitan Building Act, the text of the Act, by-laws of the County Council, regulations, brand marks, and other information of a general kind, of which all students of Laxton are familiar.

#### ZINC CEILINGS.

THE large use of zinc and sheet metal for architectural ornamentation in America and Australia is one of the notable facts which the records of contemporary buildings in those countries brings to our notice. Cornices, window dressings, Mansard and other roofs, dormers, and ornaments are largely formed of sheet metal, fixed upon brackets to the walls, or otherwise secured to the structure. Unfortunately, we have no definite information as to the durability of this sort of architectural decoration, though, judging from English experience of metalwork and zinc applied externally, there is little promise of the permanence of these appliances. In Sydney zinc appears to be used for ornamental ceilings, and a ceiling of this kind on a rather large scale has been recently fixed in an hotel dining-hall at Sydney, which for richness of ornamentation and "beauty of design" is said to be unrivalled. The ceiling is divided into 15 deep and rich panels, "handsomely decorated and gilded." The chief advantages of a zinc ceiling are that it can be soon fixed without dirt, and is a comparatively light material. Certainly, its internal employment is more likely to be a success than its external application. The metal can be moulded into panels or coffers, and fixed up in large pieces, and the material can be decorated or gilded. Moulded zinc cornices can be fixed *in situ*. The

acoustical properties of the material is a point that has to be tested. One thing in its favour is its durability. We are not aware that metal ceilings have been employed in this country to any extent, though there are many substitutes for plaster. One question is the fixing of the sheets, and the allowance to be made for expansion and contraction. To cover old ceilings, or to prevent the appearance of cracks, the metal ceiling is well adapted, as the sheets can be easily fixed, care being taken to prevent the unpleasant rattling of the sheets from vibration or shaking of the floor.

PRACTICAL ARCHITECTURE WITH  
DETAILED ESTIMATES.—LXII.

By HENRY LOVEGROVE, F.S.I., Surveyor.

ESTIMATE FOR A VILLAGE ELEMENTARY SCHOOL.

BELL TURRET (Continued).

ft. in.	ft. in.

12		External mitres.
		L.E.

The vestry of St. Martin-in-the-Fields, Westminster, proceeded on Thursday, the 20th inst., to elect a surveyor. There were 85 candidates, out of whom eight had been selected by a committee, and from these Mr. Charles Mason, A.R.I.B.A., assistant borough surveyor of Leicester, and late of Nottingham, was appointed.

The Duke of Westminster on Saturday opened the headquarters, which have just been completed, for the 2nd Middlesex (Customs) Artillery, in Leonard-street, City-road.

#### CAMBERWELL INFIRMARY EXTENSION.

THE new building, forming the extension of the Infirmary in Havil-street, is now completed, and is being rapidly prepared by the Board of Guardians for the patients. The new building, which is circular on plan, contains room for about 105 beds, including dormitory accommodation for nurses and a few cases requiring special treatment. There are four stories, each containing a ward for 24 beds, together with a nurses' kitchen, lavatories, bath, w.c.'s, and other conveniences. Also externally tiers of wrought-iron galleries, about 100ft. in length, connecting each floor with the present infirmary, and forming both ambulatories for air and exercise for convalescent patients, and, being fireproof, affording an additional mode of escape in the event of fire. Two lifts are also provided, the larger one for patients, actuated by hydraulic power, the smaller for coals being a hand-power lift. Dust and soiled-linen shoots are also provided. The floors are fireproof. The water storage for lifts, domestic, and heating apparatus is contained in iron tanks in a separate chamber at the top of the office buildings at the rear. The heating is obtained by means both of hot-water pipes and likewise by open fire-grates—two to each ward. The ventilation is effected by means of fresh-air inlets and foul-air vents into a central shaft, assisted by the open fireplaces, flues to which are collected in the same shaft. The circular form of the building has been adopted on account of hygienic advantages, affording, as it does, scope for the vivifying influence of the sun's rays, for the greater part of its circumference, for the ever-changing currents of air, and also because of its suitability to the nature of the site. The present pavilion or block forms one section only of the entire scheme for the infirmary, and which, when completed, would represent, inclusive of the original infirmary, a total accommodation of 700 beds, with suitable administrative

and other necessary offices. The works have been very satisfactorily carried out under Mr. Robt. P. Whellock, A.R.I.B.A., the architect to the Board of Guardians, assisted by Mr. C. Osborne, the clerk of the works, by Messrs. John Allen and Sons, of Kilburn; the contract price being £14,665, based upon quantities prepared by Messrs. Franklin and Andrews. The contract also includes sub-contracts for the following special works, viz.:—For the constructional ironwork and fireproof floors, by Messrs. Homan and Rodgers; that for the sanitary and internal plumbing by Mr. Geo. Jennings; and that for the lifts by Messrs. Smith and Stevens.

#### EDINBURGH ARCHITECTURAL ASSOCIATION.

A MEETING of this association was held on the 20th inst., Professor Baldwin Brown in the chair. Mr. Henry F. Kerr read a paper on "Ingress and Egress for Public Buildings." In Terry's Theatre the exit accommodation was sufficient for a house of four times its capacity. The Glasgow scheme of enlarging the exits for the upper floors was, Mr. Kerr, thought to be recommended. A plurality of exits for each block should in all cases be insisted on, and the exit capacity of the seat rows should also be attended to. Stairs for ascent and descent ought not to be of less width than the corridors between them and the auditorium, or wider than the corridors between them and the exterior. They should be provided with a hand-rail on both sides, and where six or more feet in width should also have a hand-rail in the centre. The straight stair was open to objection, if of any length, the square and the newel square—which doubled on itself—being the safest forms. It was desirable always, in the interests of safety, to reduce the number of steps required for access to the various parts of a building, as the danger was, generally speaking, in proportion to the number of steps to be traversed. Hence the object in sinking the

pit in theatres below street-level, to reduce the height from the street to the gallery, and hence also the merit of Mr. Tarver's plan which placed the gallery outlets at the level of the lowest seats in place of at the level of the highest. He recommended that all exit doors should be conspicuously marked as such, so that the audience might not use a door which did not lead to the outside of the building. Doors should open outwards or swing either way, and should not be secured except by some fastening which yielded automatically to pressure from within. Corridors and stairs should be kept clear of all obstructions barriers being very rarely, if ever, admissible.

#### CHIPS.

A marble tablet has been placed in the south aisle of Winchester Cathedral as a memento of the late General Sir Arthur A. T. Cunyngame, G.C.B., who died in 1883. Messrs. Newman and Son, of that city, carried out the work.

A site has been secured for the proposed new church at Wesham, near Kirkham, which is to be erected from the designs of Messrs. Paley and Austin, architects, of Lancaster, at an outlay of £2,500.

The parish church of Lyddington, near Uppingham, is undergoing restoration at a cost of over £1,200. A new roof has been put over nave, new flooring and seats are being laid, the glass in windows is being set in new lead framework, and the old screen has been cleansed from paint, while the new features include heating-apparatus, clock, and brass lectern. The church is about to be restored at the cost of the Ecclesiastical Commissioners.

The Louvre Museum has just purchased the "Portrait of an Old Woman," by the English artist Bonnington.

The partnership heretofore existing between Messrs. Isitt and Verity, of Wigan, architects, is announced in Friday's *Gazette* to have been dissolved.

NEW POST OFFICE BUILDINGS, ST. MARTIN'S-LE-GRAND—CONTEMPORARY BRITISH ARCHITECTS—SOANE MEDALLION DESIGN FOR A PUBLIC DAY SCHOOL OF 100 BOYS—CHURCH OF ST. ALBAN THE MARTYR, VENTNOR—A DRAWING-ROOM IN THE STYLE OF THE CONSULATE.—CANOPY AND TABLE FOR THE SPEAKER, PIETERMARITZBERG.—SKETCHES IN BELGIUM.

OUR LITHOGRAPHIC ILLUSTRATIONS.

GENERAL POST-OFFICE NORTH.

THESE buildings, of which we give elevations and plans, are being erected in St. Martin's-le-Grand on the site of the Queen's Hotel, the French Protestant Church, the old Money-Order Office, &c. The new buildings have frontages towards Angel-street and King Edward-street, also towards the burial-grounds on the north side. St. Martin's-le-Grand, Angel-street, and King Edward-street will all be widened. On the northern boundary stands a portion of the old City wall, the lower portion being Roman. This has been exposed to view and underpinned. The buildings have been arranged round a central courtyard, approached by carriage entrances from St. Martin's-le-Grand and King Edward-street. They will consist of seven stories, and over some portions there is an eighth. There will also be two stories under the courtyard. So far as possible, large rooms have been provided, together with ample staircase and lift accommodation. The area of the floor space, apart from corridors, staircases, &c., is 152,820sq.ft. The buildings generally will be faced with Portland stone; but in the courtyard glazed brick will be freely used, and Leicestershire bricks will be used throughout. All floors will be of concrete with steel joists, and the roofs will be flat and asphalted. The external doorways will be of polished granite, also the columns to the entrance roadway from St. Martin's-le-Grand. This entrance has a barrel vault with stone ribs. The contract for the foundations and lower portion is nearly completed, and has been carried out by Messrs. Brass and Son, Mr. Leake being the clerk of works. Mr. Henry Tanner, of H.M. Office of Works, is the architect. We shall publish some details of the main parts at an early date.

CONTEMPORARY BRITISH ARCHITECTS.

See description on p. 326.

PUBLIC DAY-SCHOOL FOR BOYS—R.I.B.A. PRIZE MEDAL DESIGN.

It will be remembered that in the recent Soane Medallion competition at the Royal Institute of British Architects, the Council considered that no one design submitted was, on all points, however admirable in some, worthy of the £50 and Medallion. Two medals were therefore given by the Institute to the authors of the first and second designs mentioned in the report of the judges. Both of these designs we are to illustrate, and we give the view and plan to-day of Mr. Charles Spooner's design, to which the second medal was awarded. His plans were not equal to the merit of his elevations, on which he certainly deserves congratulation, and we think he entirely merited the prize he won. We hope to illustrate Mr. Francis W. Bedford's first-medal design next week.

CHURCH OF ST. ALBAN THE MARTYR, VENTNOR.

THE site of the church is on the side of a steep hill, having a fall of about 23ft. from north to south. The approaches are from a roadway on the south, and from a steep footway, inaccessible for carriages, on the west. The level of the nave floor has been fixed rather higher than midway on the slope of the ground. The southern doorways will be reached by inclined paths and steps. The church, when complete, will consist of a nave, with north and south aisles, chancel, with clergy and choir vestries, on the south, and an organ-chamber on the north. The tower, forming a porch, is placed at the west end of the south aisle. The chancel will be separated from the nave by a high oak screen on a stone base. The choir seats are planned with returned stalls. The altar will be well raised above the nave, and the eastern windows placed high in the wall to allow of a lofty reredos. The whole of the walls have been built to the level of the nave floor, and the superstructure is about to be proceeded with. Grey ragstone is being used for the external facing of the walls, and hard freestone for the dressings—both stones being quarried in the locality. The architect is Mr. Chas. R. Baker King, of London.

A DRAWING-ROOM IN THE STYLE OF THE CONSULATE.

THOSE of our readers who have a knowledge of photography will appreciate the difficulty, successfully overcome as we hope, of reproducing in monochrome, a drawing in which strong yellow plays so conspicuous a part as in the present example. The ground colour of the wall panels is yellow, with coloured arabesques thereupon. The borders are in two shades of grey-blue. The ornament of the frieze is gold on a deep blue ground. The soffits of beams, two greys, and a small quantity of orange on cream colour. The ceiling panels are bordered by two shades of blue, lighter than that used for the walls, with variously coloured filling. Pilasters, red at the lower part, white and gold flutes above. The furniture and doors are darkened, polished mahogany, with brass mounts. The settees and easy-chairs are covered with a silk of which apricot is the prevailing colour. The dado is in dark greenish greys, with lighter-coloured mouldings. The original drawing, which was in the last Exhibition of the Royal Academy, is by Mr. Walter Hensman.

The new clock and chimes at Sunderland municipal buildings, which have been erected from the designs of Mr. Brightwen Binyon, of Ipswich, were formally started last week. The time is shown on four external cast-iron dials on the tower of the town hall. The hours are struck on a bell weighing about four tons, and the quarters by five hammers on four bells of about 3½ tons, making the total weight of bells 7½ tons. The clock was constructed by Messrs. Wm. Potts and Son, Leeds, and it is similar to those in Rochdale and Bolton town halls. The bells were supplied by Messrs. John Wainer and Son, bell-founders.

Mr. Frederick Jopling, C.E., engineer to the Tees Conservancy Commissioners, died last week after an illness of a few days. Mr. Jopling was a son of the late Mr. T. T. Jopling, of Sunderland, and came to Stockton as assistant to the late engineer, Mr. Jno. Fowler, at whose death he received the appointment of engineer. The deceased gentleman, who was only 35 years of age, leaves a widow and one child.

Acting under instructions from Mr. J. Wolfe Barry, of London, Mr. James Fraser, C.E., Inverness, arrived at Stornoway on Friday night to make preliminary surveys and investigations of some of the proposed works in Lewis, for the information of the Commission of experts who are shortly to proceed north to take evidence. Among the matters which will first receive attention from Mr. Fraser are the proposed harbour at Carlaway, the alternative schemes of an improved road and light railway or tramway from Stornoway to Carlaway, and the proposed harbour at Gress.

William Morris, the decorative artist and poet, has consented to give a lecture on "Gothic Architecture," at the Liverpool Artists' Club, on Saturday, April 12. In accepting the invitation, he writes:—"I fear that talking about the 'arts' to people in Liverpool is rather a waste of time, as they cannot have them there, or any beginning of them, until they have pulled Liverpool down to the ground and started practical equality among men."

The sewerage of the village of Abbots Langley, Herts, was commenced last week. Mr. H. Busby is the contractor.

CANOPY AND TABLE FOR SPEAKER'S CHAIR.

THE Canopy for the Speaker's Chair, which forms the chief subject of this illustration, has just been made by Messrs. Walker and Sons, of Bunhill-row, London, and was recently sketched at their works. It is designed for the Legislative Chamber at Pietermaritzberg, Natal, by Mr. F. W. A. Watson, a local architect, and is made to match the existing chair. The whole has been executed in teak, including the soffit of canopy and the panelled back. The British coat of arms surmounts the whole, emblazoned in colours and gold, the Natal coat of arms being contained in a cartouche in the long panel, with crown over. The greater portion of the back is covered with a dark crimson pleated cloth. The table is also made in teak, and is fitted with a sloping lift-up top to form writing-desk.

SKETCHES IN BELGIUM.

THE accompanying drawing represents a few buildings sketched during a trip to Belgium in the autumn of 1889. Bruges is too well known to need any description; but Dinant is perhaps, less visited. It is a pretty little town of about 6,400 inhabitants, and very pleasantly situated on the banks of the Meuse, 18 miles above Namur. The 13th-century church, with its double tower and bulbous spire, stands at the foot of a steep citadel-crowned cliff. From Dinant an interesting walk may be taken to the French frontier fortress, Givet, passing on the way the picturesque church and farm (combined) of Anseremme.

WILLIAM H. KEEL.

CHIPS.

The Education Department for Scotland have approved of plans prepared by Mr. John Robertson, of Inverness, for a new academy for 200 pupils to be built at Fortrose, close to the ruins of the old cathedral.

A new boulevard for Buxton, constructed at a cost of £1,200, was opened for the public use on Monday. It is called the Burlington, and is 1,600ft. in length, connecting with the Broad Walk, St. John's-road, and the park, the most fashionable quarters of the town. The Duke of Devonshire is about to parcel out sites overlooking the gardens, whereon villas will be erected.

The hangers appointed for the forthcoming exhibition at the Royal Academy will consist of the following painters:—Sir John Millais, Briton Riviere, Edwin Long, J. B. Burgess, and W. W. Oulless; H. H. Armstead, sculptor; and J. L. Pearson, architect.

New board schools, to accommodate 372 children in two departments, are to be built at Leigh, near Southend-on-Sea, at a cost of about £4,500. Mr. W. J. Wood, of Finsbury-circus, E.C., is the architect, and Messrs. Darke and Son, of Southend, are the contractors.

For the erection of a fountain in the village of Hawarden, in celebration of Mr. and Mrs. Gladstone's golden wedding, the design by Mr. E. Griffith, sculptor, of Chester, has been accepted. The fountain will be 16ft. in height, and surmounted by a lamp. It will be executed in Manley and Stourton stone, and will be circular in plan at the base, and above that level; triangular.

The town council of Faversham have elected Mr. Power as borough surveyor in succession to Mr. T. Ware, resigned, who has been appointed consulting surveyor.

A mural monument has been erected, at a cost of nearly £1,000, in the chancel of Llanbader Fawr Church, Cardiganshire, in memory of the late Colonel Pryse, Lord-Lieutenant, and for some time Member of Parliament for the county.

The Aberdeen art gallery is to be enriched by a presentation portrait of Mr. W. A. Hunter, M.P., to be painted by Mr. George Reid, R.S.A.

A font has just been placed in the Early English church built at Westward Ho! twenty years ago. It stands upon a raised dais of Portland stone, and the bowl and base are of Caen stone, the former being supported by clustered columns of red Corse-hill stone. Mr. Harry Hems, of Exeter, carried out the work from the designs of Mr. W. Oliver, of Barnstaple.

The tender of Messrs. Parnell and Son, of Rugby, has been accepted for building a new mansion at Springfield, Kent. Thirteen firms sent in tenders, and the building will cost upwards of £20,000.

The columns in the Mosque of Achmed, published by us last week, by a clerical error were described as being 3ft. diameter. It should have been 36ft.

## WAYSIDE NOTES.

I WAS interested in Mr. T. K. Oliphant's drawings of Danbury Church, Essex, which you reproduced last week. They cause me to remark that if, in more instances, those who go about the country sketching and measuring old work would give us their original rough sketches, rather than finished scale drawings, that may or may not be truthful representations of the building and its parts, it would be more to our profit. If not always to our profit, it would without doubt be to our pleasure, as it is pleasant to be able to follow the very touch of the draughtsman or sketcher. This one can do in a drawing made on the spot. From an examination of the method of delineating features and details, one can more accurately judge the character of the original work, and this would seem to be especially true of outlines and mouldings. A smart set of black-and-white plans, elevations, and sections have an imposing effect; but it neither evidences want of faith on one's own part, nor direct misrepresentation on the draughtsman's side, to very frequently feel dubious as to their accuracy. Not that I would do away with a line of the many sheets of scale drawings of measured work that we—thanks to the enthusiasm of others, and cheap methods of reproduction—are yearly able to enjoy. All I would ask is that sometimes sketchers will follow in Mr. Oliphant's footsteps, and give us rough sketches in preference to finished drawings.

I take it, of course, that these sketches were made on the spot, and are not merely home-made drawings. If there is one manner of sketching calculated to improve the "touch," and conduce to care and accuracy in detail and proportion, it is sketching in ink from the actual building. But the sketcher must be conscientious, as it is easy for clever people to make fine drawings that are about as like the actual thing as the speculative builder's elevation is like the surveyor's design. In sketches made on the spot, too, there is a freshness and crispness that gets "refined out," so to speak, in re-drawing. For all reasons, therefore, I would see a larger share of attention paid to this class of sketching. I do not refer to perspective sketches, but to elevations, plans, and sections, with a view to the preparation of accurate scale drawings. These sketches may be so prepared, by those practised in the art, as to be really beautiful specimens of workmanship, and not mere sheets of rough scrawls and notes. Students may depend upon it that studies of this nature are more productive of the power of designing with a crisp and artistic touch than any other kind of disciplinary exercise.

Mr. Albert Goodman delivered a very interesting lecture at the Society of Architects on Tuesday evening. Even if we cannot all agree with the views expressed, and refer the sense of the beautiful directly to the matter-of-fact construction of the eye and its muscles, the remarks of Mr. Goodman were such as are provocative of thought, and in some senses discourses of this nature are the most valuable of all. As regards the accuracy of the theories deduced, it is certainly very apparent that throughout nature, the most beautiful attributes of any material creation, are connected with some prosaic, matter-of-fact purpose. One can therefore believe that our sense of beauty of form is dependent upon the system of muscles that move the eye. But when all is said in this direction, the fact remains that beauty appreciated in this manner is but the cold, dry-as-dust beauty of the marble statue. The appreciation of the most beautiful forms, as of the most beautiful feelings and sounds, is referable to the emotions springing from the heart of man. This doesn't seem very clear to the reader, perhaps—it is hardly so to myself (!) and reminds me of the man who, on being asked the meaning of a certain passage in his book, said that at the time he wrote it only two persons could understand it—God and himself. "But now," said he, "God only knows."

Anyhow, even if one feels that, in future, a man who perpetrates an architectural monstrosity should come under the criminal law for inflicting injury upon the muscles of the eyes of the community, and that therefore Lord Grimthorpe should by this time be in durance vile, and, further, that the lecture at the Society of Architects has tended to destroy the poetry of our art,

yet I repeat that original lectures like that of Mr. Goodman are interesting, and lead one's thoughts into further research of problems in connection with design and composition. As such, therefore, let us accord them a hearty welcome.

We shall be getting quite Classic again, if the abundance of lectures and papers on Greek and Roman art and architecture is to continue. We have had some admirable discourses on Roman architecture by Professor Aitchison, and the students at the Royal Academy should begin to get something more than a smattering of the subject, since the lectures on Roman houses and other matters pertaining to the palmy days of the old Empire are full of information. Touching Classic architecture, we have had a paper from Mr. R. Elsey Smith that contains passages calculated to make us forswear the "Gothick" manner of building for ever, and live only to see the Propylæa and its wonders, and die—after, that is to say, comfortably "doing" the place.

There will not be another Classical revival such as that of the beginning of the century. The façades of the Parthenon that adorn (?) London thoroughfares in every part of the city, are a sufficient safeguard against the folly of reproducing for the sake of reproduction, and without any definite end in view other than an exact model of an ancient temple. Nevertheless, Classical studies should be persevered in with redoubled vigour. It was the "little knowledge" which is a "dangerous thing" that induced men to erect temple façades over grocery stores and butchers' shops. Since the Revival days we have learned that the old Greeks and Romans were not such fools as they would have been had they designed their buildings as the Revivalists imagine they did. Fertility of imagination, we are justified in supposing to-day, was as rife on Classical soil as in Medieval times, and it was left for wiseacres of the last generation to follow Palladian and Vitruvian principles and deduce therefrom certain arbitrary rules of proportion. To my mind, Grecian and Roman architecture should be viewed by architectural students in the same way as the general student regards the old Greek and Latin tongues. The latter do not want us to *speak and write* in a dead language, and the former should not think of slavishly copying an architecture which is no less dead.

There was considerable divergence of opinion at Tuesday's meeting of the County Council when the subject of the proposed Blackwall Tunnel came under discussion, advocates of *pro's* and *con's* being equally enthusiastic and positive. There is undoubtedly much to say for the free steam-ferry idea. If it could be shown that accommodation of this nature could be provided sufficiently ample to meet the demands of the traffic that it is said would be found to utilise any means of transit of the river in this district, then certainly it would be well to prefer it to a tunnel or bridge. And two large steam ferries of the type to be found lower down the river could accommodate a good deal of traffic—if, that is to say, both were to be kept going. There are, perhaps, objections to this scheme from the point of view of navigators on the river; of these I do not know. All that an independent observer can see is that the tunnel will cost a vast sum of money, and that a bridge of sufficient elevation to clear the masts of large ships is impracticable. A system of steam ferries, therefore, seems to recommend itself. I do not see any suggestion of a bridge on the principle of the one now being built near the Tower, and am a little surprised at this. Not that it is anything to regret. It has yet to be shown how the Tower Bridge is to answer in practice, and whether a person will not look upon the journey on to the bridge up one tower across the high-level bridge, down the other tower and over the remaining portion of the low-level bridge, as an undertaking on a par with a journey across the Atlantic. GOTH.

A new club has been erected at Hayes, Middlesex, and special attention has been paid to the ventilation, the extraction of the vitiated air being effected by Messrs. Robert Boyle and Son's latest improved patent self-acting air-pump ventilators, and fresh air admitted by their improved air inlets.

The Petersfield Gas Company purpose making extensive alterations and additions to their works. Mr. John Chadwick, C.E., architect, Petersfield, has been appointed engineer to carry out the same.

## COMPETITIONS.

BIRMINGHAM.—The Free Libraries Committee of the Birmingham Corporation have selected plans submitted for new branch free libraries in Lingard-street and Summer-hill. The site of the former is at the corner of Salliey-road, that of the latter at the junction of Summer-hill with Icknield-street. The Salliey design is the work of Messrs. Cossins and Peacock, and is Renaissance in style, has a clock tower, and is to be carried out in brick and terracotta; the other (a Gothic design, also to be executed in red brick and terracotta) is by the firm of Martin and Chamberlain, all of Birmingham. The committee also approved of a provisional purchase of land for a branch library at Small Heath, and it is proposed to acquire sufficient land here to allow of the erection not only of a library, but of baths on the site.

READ AND LIMONSTONE CONSTITUTIONAL CLUB.—The plans of Mr. V. Dunkerley, architect, of Burnley, have been selected in a limited competition for the above club. On the ground floor are smoking, card, and store-rooms, together with a large reading-room; the first floor is occupied by a billiard-room for two tables, lavatories, &c.; in the basement is placed the heating chamber and cellar for storage. The elevation is of a substantial character, and will be built of local stone. The work is to be proceeded with at once.

LEEDS.—The town council have adopted Mr. W. H. Thorp's plan for enlarging the Victoria Hall from among nine designs received in competition. Mr. Thorp proposes, by means of an end gallery and a series of side balconies, to provide 636 ordinary sittings and 141 flap seats. This will not involve the projection of side balconies beyond the line of the existing pillars. The glazed screen dividing the gallery from the vestibule is to be set back to the arched opening adjoining the vestibule. The gallery will be confined within the limits of the first bay of the hall. It will be bow-shaped, and narrowest opposite the side entrances. Two large crush-rooms at the gallery end of the hall will be provided. The cloak-room and lavatory accommodation in connection with the Mayor's suite of rooms is to be entirely remodelled. The work generally will be carried on in fireproof construction, having rolled iron joists, filled in with coke-breeze concrete. The gallery and balcony fronts will be of cast iron, carried out to special ornamental design and afterwards gilded and decorated. The estimate for the work, exclusive of seating, is £2,560.

SOUTH STOCKTON-ON-TEES PUBLIC BUILDINGS.—The prizes in the competition for new public buildings for the local board of this town have been awarded as follows:—First premium, Mr. James Garry, 1, Church-street, West Hartlepool; second, Messrs. Edeson and Rowntree, Scarborough; third, Mr. H. Weatherill, Stockton. Messrs. Bell and Roper, of Manchester, and Mr. George Styant, of York, were highly commended for their plans. There were 25 competitors. The total cost is estimated at £4,000, including site and furnishing.

STRATHPEFFER.—The committee for the erection at Strathpeffer of an Episcopal church, as a memorial of the late Duchess of Sutherland, have selected from a list of three the designs submitted by Mr. John Robertson, architect, Union-street, Inverness. The other architects in this competition were Messrs. Ross and MacBeath, of Inverness, and Mr. Joan, of Dingwall. The church is arranged to accommodate over 300 sitters, independent of choir; and is designed with nave, aisle, baptistery, chancel, choir, organ-chamber, clergy and chorister's vestries, heating-chamber, and entrance porches. The circular bell-turret, a special feature of the design, is prepared for a chime of bells. The open roof will be of dressed pitch-pine, while the choir seating, reading desks, lectern, and litany desk will be of cedar wood. It is to be built throughout of stone from the estate.

SWANSEA.—In the recent competition of architects for rebuilding the "Welcome" Hotel, High-street, Swansea, six designs were submitted by architects. The one bearing the motto "Well Considered" was accepted, the authors of which are Messrs. James Buckley Wilson, F.R.I.B.A., and Glendinning Moxham, M.S.A., architects, of Swansea.

# CONTEMPORARY BRITISH ARCHITECTS.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

THE seventh double-page photo-lithographic plate of living architects is given herewith to-day, and the accompanying notes refer to those who are thus represented and grouped together. The arrangement of the portraits necessarily depends very much upon the date at which they were received for reproduction.

Mr. G. C. Ashlin, R.H.A., was a pupil of the late Mr. E. Welby Pugin, and, at the termination of his articles, became his partner in Ireland. The principal works carried out by him in conjunction with Mr. Pugin up to 1872, and since then on his own account, were SS. Peter and Paul's Church, Cork; Queenstown Cathedral, the Magdalen Asylum Building, Sunday's Well, and the Clonakilty Church, Co. Cork; the Augustinian Church and St. Kevin's Church, in Dublin; and churches at Donnybrook, Monkstown, Glashule, Rathfarnham, Dundrum, Tal-laght, St. Alphonsus, Clonliffe, and Raheny, in the neighbourhood of Dublin; several churches in the provinces, the most important being the O'Connell Memorial Church, Co. Kerry; churches at Carrick-on-Suir, Kilfinane, Emly, Templemore, Tralee, Delvin, Drogheda, Newry, and Dundalk. His principal domestic works were Tillyra Castle, Co. Galway, for Mr. Martyn; additions to Ballynastragh, for the late Sir John Esmonde; a Gothic bridge and other works at Ashford, Co. Galway and at St. Anne's, Clontarf, for Lord Ardilaun. He was the architect of the Dublin Exhibition Buildings of 1882, and of the Cardinal McCabe Memorial at Glasnevin. Mr. Ashlin has erected the Sun and the Northern Insurance Offices and other commercial buildings in the city of Dublin. He is a member of the council of the Royal Institute of Architects of Ireland, and a member of the Royal Hibernian Academy. The portrait is taken from a photo by Mr. Lafayette, of Dublin.

Mr. Edward Joseph Hansom, F.R.I.B.A., the President of the Northern Architectural Association, is the only son of the late Mr. Charles Hansom, of Clifton, Bristol, under whom he studied his profession, and in the year 1867 became a partner with his father. At this time many important works were carried out—viz., the Clifton and Malvern Colleges, and the Kelly College at Tavistock; St. Paul's Church, Clifton; St. John's Church, South Parade, Bath; the Franciscan Convent, Woodchester, &c. In 1871 Mr. Hansom left Bristol to join a former pupil of his father's Mr. Archibald Dunn at Newcastle-upon-Tyne, and the firm of Dunn and Hansom have carried out some of the most important Roman Catholic buildings undertaken since that date. Among others, the new college buildings at Stonyhurst, also at Downside, in Somersetshire, where a monastery and church are partly built, on a scale which will some day cause it to rival its Mediaeval prototypes; St. Bede's College, Manchester, and the first Diocesan seminary erected in England, at Olton, near Birmingham, for the late Archbishop Ullathorne. Among churches in Newcastle and the neighbourhood are St. Michael's, Elswick, and the spire of St. Mary's Cathedral, the new Collegiate Church at Ushaw, Washington, Burn-opfield, Monkwearmouth, &c.; St. Catherine's, Birmingham, and others at Harborne and West Bromwich; St. Mary's, Bath, and the new R.C. Church at Cambridge, now approaching completion. Many schools, presbyteries, &c., have been carried out; two for the Newcastle School Board. Last year they completed the new buildings (in Newcastle) of the "University of Durham College of Medicine."

Mr. Thos. N. Deane, R.H.A., is a son of Sir Thomas Deane, who was also an architect, and whose father and grandfather and brother followed the same profession. The works of Mr. Thos. N. Deane, as partner in the firm of Sir Thomas Deane, Son, and Woodward, were the Museum, Trinity College, Dublin; the enlargement of the library at Trinity College, and the museum at Oxford, as well as the debating-room of the Union, Oxford. Mr. Thomas N. Deane designed the new buildings in Broad-walk, Oxford; Christ Church College; Sir B. Brodie's house, Oxford; the chemical and physical laboratories at the Museum, Oxford; the Crown Life Office in Fleet-street, London, and another insurance office in New Bridge-street, Blackfriars, also in the Venetian Gothic style; Lord Clanricarde's Castle, Portumna; Tuam Catho-

dral; restoration Kilkenny Cathedral; restoration Kilkenny Castle; seven insurance offices in Dublin; the Munster Bank, Dublin. He also took part in the great competition for the Law Courts, London. In conjunction with his son, Mr. T. M. Deane, his present partner, the firm have carried out the Museum of Science and Art and National Library, Dublin, which was won in competition; various branch offices through Ireland for the Provincial and Munster Banks have been erected by them: the Royal Exchange Insurance Office, Dublin; the Commercial Union Insurance Offices, Dublin; the town hall and markets, Bray, co. Wicklow; the rebuilding of Lough Crew House, co. Meath, for Mr. J. L. Napier, D.L.; the M'Arthur Hall, Belfast; and various country houses in several parts of Ireland. Messrs. Deane and Son's design submitted in competition for the Imperial Institute, will long be remembered for its ability and the grandeur of the scheme. The Anthropological Museum and the Physiological Laboratory at Oxford are among their recent works, and also a house for Master Bruce near Dublin; the Church of Ireland Training College, Dublin, and other works of more or less importance have been finished from their designs. Mr. Deane is superintendent of Ancient Monuments in Ireland, under Sir John Lubbock's Act, also under the Church Act. He is a member of the Royal Hibernian Academy, and Lecturer on Architecture to the Science and Art Department, Dublin. His portrait is by Messrs. Werner and Son, of Dublin.

Mr. Arthur Cates, F.R.I.B.A., Vice-President R.I.B.A., was a pupil of Mr. Sydney Smirke, R.A. In 1852 he entered the office of Mr. James Pennethorne, with whom he remained till 1859. In 1870 he accepted the instructions of the Commissioner of H.M. Works in charge of the Crown property in London, to which his attention has since been almost exclusively devoted. He is also Surveyor to the Inner Temple, and has been Chairman of the Board of Examiners in Architecture since its establishment in 1882. Mr. Cates has designed and carried out numerous commercial and other buildings in London, in Fleet-street, the Temple, the Strand, Piccadilly, Jernyn-street, in Shoreditch, and elsewhere. His work in connection with the cause of Architectural Education has been carried on with great energy and much usefulness for very many years, and in the capacity of Hon. Sec. to the Architectural Publication Society he has had a large share in the production of the still unfinished Architectural Dictionary. Mr. Cates's photograph is by Mr. Bassano, of Bond-street, W.

Mr. Robert Walker, A.M.Inst.C.E., is President of the Society of Architects. He is the son of the late Mr. Walker, who was city surveyor of Cork for forty years. From 1851 to 1854 he served his time with the late Alexander Deane, architect, and with the late Sir John Benson, who was consulting architect to the Corporation, and engineer to the Cork Harbour Commissioners. His master also had a large private practice. From 1854 to 1859 Mr. Walker had charge of the architectural practice of Mr. Henry Clutton, F.R.I.B.A., of Whitehall-place, during which time he built several churches, mansions, schools, villas, farm buildings, &c. In 1860 Mr. Walker commenced independent practice at Cork, his earlier works being the National Cattle Show buildings at Cork, residence at Farren, and sundry small works and villas, additions and reconstruction of St. Fin Barre's Brewery, Turkish bath, Glebe House, Masonic Hall, Co. Cork, some Wesleyan chapels, warehouses, bacon factory, and printing works in Cork; Munster Arcade additions: a large residence, Queenstown; Wesleyan Chapel, Kinsale; large additions Cork City gaol; warehouse, 30, Patrick-street; Tralee Lock Gates; large bacon factory, Hamburg; Parliamentary plans, Cork bridges; mill, Kenmare; skating rink, distillery, brewery, and two hotels in Cork; St. Peter and Paul's schools for 900 children, and Presbytery, Cork; additions to some premises at Hamburg; Holy Trinity Church choir, Cork; new convent, library chapel of 3rd order, &c., Cork; and a doctor's residence, Barrow-in-Furness. In 1883 he designed the International Exhibition at Cork; the Methodist Central Hall, also at Cork; additions to Clairville, Reigate; bread factory, Cork; large bacon factory, Cork, for Messrs. Lunham Bros.; additions and alterations to Queen's Bacon Factory, for Messrs. J. J. Richardson, Waterford; additions to Lady's Well Brewery, Cork; Gresham Life Assurance Society offices, Cork, and many other works of

less importance. Mr. Walker's photograph is by Messrs. Guy and Co., Limited, of Cork.

Mr. Macvicar Anderson, Vice-President of the Royal Institute of British Architects, was associated with the late Mr. Burn, and succeeded to him in his practice. Among his new buildings we may enumerate the following:—Lockerley Hall, Hampshire; Meaford, Staffordshire; at Kimbolton Castle, Huntingdonshire, for the Duke of Manchester; Cheswardine, Shropshire; Sandhills, Surrey; Hedgecroft, also in Surrey; King's Beeches, Berkshire; and Highwoods, in the same county; at Lynford Hall, in Norfolk; Branstons Hall, Lincolnshire; Iden Manor, Kent; a country house in Russia for the Prince Scherbatoff; Doonside, Ayrshire; Moncorvo House, London; 17, Dover-street, W., for the Marquis of Anglesey; 14, Berkeley-street, W., the headquarters of the London Scottish Rifles; St. Columba's Church, for the Church of Scotland; Bank, 62, Lombard-street, E.C., for the Commercial Bank of Scotland; Union Discount Company's Bank, Cornhill, E.C.; and the Union Bank of Australia, Melbourne. Among the alterations and additions carried out by this architect are—Somerley, Hampshire, for the Earl of Northampton; Hartley Grange, in the same county; Weston Park, Shropshire, for the Earl of Bradford; Willey Park, Salop; Sundridge Park, Kent; Oxon Hoath, Kent; Wildernesse and St. Clere, also in the same county. Orwell Park, Suffolk; Criche, Dorset; Spey Park, Barrington Park, and Hartham Park, Wiltshire; Bowhill, Selkirk, for the Duke of Buccleuch; Patshull, Staffordshire; Blankney, Lincolnshire; Wellingore Hall, in the same county. In Yorkshire Mr. Macvicar Anderson altered and added to Wortley Hall, Hainton Hall, and Nostell Priory; Althorp Park, in Northamptonshire, for Earl Spencer; Osberton, Nottinghamshire; Broxbournebury, Hertfordshire; Crookham House, Berkshire; Rocheath, Sussex; High Ashurst, Surrey; Thorndon Hall, Essex; Inverloch Castle, Inverness-shire; Powerscourt, Ireland, for Lord Powerscourt. In London his works include alterations to the Naval and Military Club, the Windham Club, the Carlton Club, the Junior Carlton, and Brooks's. The premises of the Royal Institute of British Architects were altered by him. For many years Mr. Anderson was hon. sec. to the Institute. One of his last works is the restoration of the church of St. Mary-le-Strand, lately reopened. The photograph is by Mr. Bassano, of Bond-street, W.

N.B.—We are requested to state, with reference to the works mentioned in connection with the portrait of Mr. Thomas Verity, that Mr. Hunt, his late partner, had nothing to do with the "Nouvel Hôpital Français"; but that he was principally concerned in the erection and design of the Scarborough Spa Buildings, Nottingham Municipal Buildings, and the Agricultural Hall, Islington.

## THE ROYAL SCOTTISH ACADEMY.

THE sixty-fourth exhibition of the Royal Scottish Academy this year is exceptional, inasmuch as it inaugurates a new standard of selection, a more restricted space for pictures, and some other novelties of minor importance. The council, it is well known, have been long meditating some changes in their management, and the result of their deliberations has been formulated in the revised charter now under consideration of the Privy Council. The institution has prospered in a measure, but somehow or other not entirely to the satisfaction of a critical section of its own members and the public, who affirm that this is so because it has not worked on the lines indicated by the original charter, and has never been what it was intended to become, a great national institution. Its influence has been provincial and local mainly, and its exhibitions not superior to similar collections in the larger cities of the empire. Up to a certain standard, and only within the limits of painting, has its education or influence been felt; and there is nothing to induce ambitious students, after reaching a certain stage, to remain under shelter of its wing.

These critics must recognise in the new departure a step in the right direction. The result is apparent in the higher standard almost everywhere manifest in this collection, and in the more comfortable aspect of the several apart-

ments. The architectural section has had fair consideration, and all the subjects seem to be placed at good advantage for inspection of details. This result is attained by giving them place both in the north and south rooms—in the former with the water-colours, and in the latter opposite the sculpture, which is now arranged in a line in front of a specially selected drapery on the wall. The small octagon makes a good tea room, and the larger apartments have been decorated with palms.

In addition to these novelties of arrangement, the collection has the additional attraction of containing a larger contribution than usual of interesting works by artists of other schools. Of these one at least may be classed as work of the highest art—344, "The Prodigal Son," by J. M. Swan—which will no doubt be as fully appreciated here as it has already been in Paris and London. There are two characteristic samples of W. R. Orchardson—28, "The First Dance"; and 190, "Mariage de Convenience After." J. Pettie sends three portraits; the most interesting to the public will be the likeness of the popular author, H. R. Haggard (296). The subject is represented with an upward glance of the pale blue eye, and evidently off to dream of fairyland. Sir John Millais's "Last Rose of Summer" (271) is also here; and a comic piece by Briton Riviere (178), "Of a Fool and his Folly there is no End," where a jester on a donkey has put to disorderly flight, and down a steep descent, a company of heavily-armed horsemen, who naturally are indignant at the joke being carried so far.

The portraiture occupies a very large and conspicuous portion of the space; but, as a whole, it is rather inferior to the collection of preceding years. Mr. G. Reid has nothing but portraits; and of these the largest and the most carefully-finished is the likeness of Mr. McKenzie, of the Scottish Widows' Fund, whose stately figure, so well known in Edinburgh, is here excellently posed; whilst all the other details, which make not only a true but pleasant likeness, have been carefully studied and successfully portrayed. 197, his portrait of Lord Shand, is not so good. It is a small picture, and lacks dignity and sharpness of detail. Mr. Reid's other works are presentation portrait of Sir R. Menzies, Dr. Gloag (late Moderator of the General Assembly, E.C.), Mr. T. Brodie, and Professor Frazer, who has in the official crimson, and appears perhaps to less advantage in this costume, the background being rather light for good effect. Mr. R. Gill (292) gives all justice to his subject, the Rev. James Morrison, an author of high standing, and founder of a modern sect. Mr. Otto Seyde has six portraits as his contribution, of which the most important is a large presentation portrait of Dr. Mitchell, of South Leith. One of the best specimens is 45, portrait of Mrs. Lane, by Hugh Cameron.

Figure subjects are very numerous and interesting, and the ideal has not been neglected. 403, by G. O. Reid, is one which makes its mark in this department as one of a very high class—"Voltaire at the Café De Procopée listening to the criticism of his play of Semiramis." There are about 30 figures in the piece, and six or seven nearly complete studies in themselves. Voltaire has dressed himself as a clergyman, and sits in a dark corner with a newspaper, in the left foreground, the glance of his eye being towards two of the principal figures, who are plainly discussing, somewhat vehemently, the merits of the play from which they have just returned. These figures are dressed in costumes of velvet and satin, and are very naturally arranged, and there is nothing of the starchy character in any of the attitudes. 110, "For the Crimea," by R. McGregor, R.S.A., is perhaps one of more general interest, and both in its conception and execution unsurpassed by any of its class. It is a large picture, with each figure complete, and the story, which is full of pathos, most powerfully portrayed, has also its humorous incident, in the contrast between the principal figure—a youth who has evidently 'listed for glory, and another, "half seas over," who has 'listed under the incentive of the sergeant's hospitality. The female figures have each their own sentiments of wonder, sorrow, and painful anxiety clearly written on the countenance. 144 may be mentioned as another curious fancy picture, "The Girl I Left Behind Me," by J. Thorburn Ross. This is a very large canvas, with Pre-Raphaelite minuteness of detail; a cottage scene, with screen of trees and a low dyke, against which the figure of a Highland soldier

stands behind the girl he is about to leave behind. The trees are impossible as represented in relation to the dyke, but the charm of the picture lies in the brilliant display of crimson fuchsias on the bank, and fanciful arrangement of the details rather than in the pose or rendering of the principal figures. 77 should be noticed as another ideal subject, if only as presenting, curiously enough, another rendering of the Prodigal Son coming to himself. It is by Harrington Mann, and is apparently a piece with symbolic meaning. The Prodigal is represented in the very difficult and awkward attitude of one who, descending a steep mountain, suddenly discovers a precipice before him and makes desperate endeavour to recover his footing, slipping away from him with every step he takes on the stony debris. The canvas is large, and the whole of it, save a mere suggestion of sky at the top, is a foreground of sloping hill, where two dark-coloured swine are basking in the light, and would look supremely comfortable if they were not reposing on so sharp an incline. 198, "Letters and Love-Letters," by C. M. Hardie, represents an interior, with papa reading his business letters at one side of the breakfast-table, and his daughter, with her own business correspondence, at the other. In 334 the artist takes a higher flight, and his "Juliet" is, in every respect, a good interpretation of character and incident. 58, "A Midsummer's Day's Dream," is a lake scene, with water-lilies and a lady in attitude of lazy repose, dreaming her love's young dream from a boat, the water and its reflection being very nicely rendered. 371, "Early Architecture," by W. Hole, is a capital family picture of children building a house of cards. In 347, "The Covenanter's Refuge," by H. J. Dobson, the refugee minister is expounding the Scripture to the cottagers. 412, "The Pedlar," by J. Blair, is another excellent cottage interior, worthy of a better place.

In landscape the collection is enriched by a great variety of works of a high standard of excellence—mostly quiet summer and autumnal studies. Nature in her grander and stormy moods is not represented; but James Archer has gone to India, and in 316, "The Himalayas from Simla," has brought back a piece of Highland scenery very like our own. The soft velvety green of the nearest hill side is the only suggestion of the neighbourhood of a tropical climate, and is perhaps rather like a piece of cloth stretched smoothly over the rock below. W. Beattie Brown, in 234, has a fine study of Scotch firs in "The Forest of Ennich among the Grampians," and their sturdy strength is much more happily rendered than his mountain mist. His other works are all from Dutch scenery. J. Smart has a number of landscapes, and in his "Cradle of Argyle, Ardchonnell Castle," gives a view of Loch Awe and its mountain surroundings. 34, "Edinburgh from the Fife Coast," by J. Riddell, is a clever piece of painting, showing the city through a veil of transparent mist, a ship with vivid white sail spread appearing in the middle distance. The water-colours and architectural section are reserved for future notice.

#### CHARLES BRUCE ALLEN.

WE regret to record the death, on Wednesday last, of bronchitis, in his 71st year, of Mr. Charles Bruce Allen, a very old contributor to these columns, and a man of whom William Burges once said, in our hearing, he had learned more from than from any other man in his life. Mr. Charles Bruce Allen was articled to Mr. Henry Thomas Wyatt, and was afterwards in the offices of Mr. B. Ferrey and Sir Charles Barry, as also in that of Mr. Thomas Cubitt, the builder. His principal service to architecture was probably the formation of the Architectural Museum, which he originated in humble fashion, but with splendid enthusiasm and earnestness, in a loft over a coal-wharf at Westminster, with the aid of Sir Gilbert Scott, Professor Cockerell, Mr. Hardwick, the Bishop of London, John Ruskin, and others. For ten years—or until the time the museum was removed to South Kensington—Mr. C. B. Allen devoted nearly his whole time and energy to it, and his disappointment at the severance of his connection with it was intense. Mr. Allen was a frequent contributor to contemporary literature, and a man of wide information and genial nature, though of strong individual opinions. He had been practically confined to his room for more than a year, in consequence of a severe

chill caught in the early part of last winter. He will be buried next Wednesday at Brompton Cemetery.

## Building Intelligence.

HULL.—The two foundation stones of the Victoria Hospital for Sick Children in Park-street were laid on Saturday afternoon. The front elevation will be in the Gothic style of architecture of an Early French character, and the administrative department will contain board-room 22ft. by 18ft., matrons' sitting-room and bedrooms, house-surgeon's room, and offices. The first floor will contain sixteen beds for boys, and a second a similar number for girls. There will also be a ward which will contain four beds for the isolation of cases of a doubtful character. At the rear there will be the surgeons' consulting and examination rooms, and the out-patients' department will consist of an entirely separate building. The external walls are of red brick, with Ancaster stone dressings. Mr. W. H. Bingley, of Hull, was joint architect with the late Mr. Samuel Musgrave, also of Hull; Messrs. George Jackson and Son are the contractors, and Mr. J. Alcrow is the clerk of works. The cost will be £7,500.

ORATORY, BROMPTON.—Of the altar of St. Philip and the Sacred Heart, of the above church, portions of which were carried out some years since, orders have now been given to the architect of the church, Mr. Herbert A. Gribble, to proceed with the work as rapidly as possible. The material to be in the rarest of marble, all carving to be in the Early Renaissance. We hope at a future date to give some illustrations of these works.

## Engineering Notes.

BURNLEY.—A deputation, consisting of the chairman of the gas committee, Mr. Button (borough surveyor), and Mr. Leather (gas manager), have returned to Burnley from London, where they have been for a week, inspecting gasworks and inquiring into the best means of laying out the £30,000 which it is found necessary to spend on the Burnley gasworks, which are becoming inadequate to keep pace with the rapidly-increasing consumption. The deputation visited the Metropolitan, Greenwich, and Beckton Works, and inspected the new system of inclined retorts largely adopted both on the Continent and in America. It is, therefore, not unlikely that the system will be recommended and adopted at Burnley.

#### CHIPS.

Bristol is about to be provided with a third theatre, Mr. Reynolds having instructed Mr. E. Henry Edwards, of that city, to prepare the necessary plans.

The Local Government Board have formally approved the scheme prepared by Mr. James Mansergh, C.E., for sewerage of the city of York, at an estimated cost of £101,000. The approved scheme comprises the re-sewerage of a considerable portion of the old city, the erection of a pumping station at the southern boundary of the city near Fulford, and the construction of sewage-disposal works immediately above Naburn railway bridge.

New premises, including manager's residence, for the Cornish Bank are to be built at Helston. The building will be placed at the corner, immediately opposite the Town Hall, where Wendron, Coinage Hall, and Meneage-streets join. The proposed structure, designed by Mr. Trevel, of Truro, will show elevations towards the streets entirely of Mabe granite.

A special meeting was held in St. John's Episcopal Church, Alloa, on Friday, when the Bishop of Edinburgh dedicated three stained-glass windows, which have been erected in the south side of the nave as a memorial of the late Earl of Mar and Kellie.

A large clock and chimes have just been erected in the parish church of Thorncombe, Dorset, which is fitted with all the latest improvements, and shows time on dials facing south and west. The work has been carried out by John Smith and Sons, Derby, who are also making a large chiming clock for Portishead church.

## ARCHITECTURAL &amp; ARCHÆOLOGICAL SOCIETIES.

**BIRMINGHAM ARCHITECTURAL ASSOCIATION.**—At a meeting of this Association, the President, Mr. T. Naden, being in the chair, Mr. W. H. Kendrick read a paper, entitled "Notes on Wood-work," which had been jointly written by Mr. Kendrick and Mr. H. H. McConnal, A.R.I.B.A. After a brief account of the history of the craft of the joiner, Mr. Kendrick described some local examples of his art—among them being the timber-built house called "The Oaks," at West Bromwich, which, apart from its artistically-grouped masses and delicate detail, is of interest from having escaped the hands of the restorer. The screens and stalls of Tong Church, near Shifnal (the latter notable for their harmony of mass and vigorous variety of detail), and the screen in south aisle of Hamstall Richmore Church, were described as examples of the Gothic joiner's work in church fittings, and the screen in the north aisle of the last-named church and the gallery in St. Peter's, Wolverhampton, as typical of the work of the 17th century. The Bishop's Throne in Lichfield Cathedral, of 17th century work, and probably erected for Bishop Hackett, was the last example described, and was noticed in detail as being particularly fine. A number of very fine drawings, prepared by Messrs. Kendrick and McConnal, gave an especial interest to the paper, and at the close of an animated discussion following the paper, a hearty vote of thanks was accorded by the meeting to the authors.

**PROPOSED CO-OPERATION OF SCOTTISH ARCHÆOLOGISTS.**—At the monthly meeting of the Glasgow Archaeological Society held on Friday night, Mr. John Honeyman, F.R.I.B.A., the president, read a paper entitled "Suggestions for Co-operation with the View of Facilitating Archaeological Works in Scotland." At the outset Mr. Honeyman explained that, owing to the exclusion of Scotland from the co-operative scheme of the Royal Society of Antiquaries, it appeared to be their duty to devise a scheme for themselves. It was impossible for any one section of the country to achieve success in the direction indicated without advantage to the others and to archaeologists everywhere. He did not pretend to bring before them a scheme matured in all its details, but only so far sketched out that it might conveniently form a basis for discussion. Their aim should be chiefly and almost exclusively the aggregation of archaeological facts—the gathering together of facts in such a way that they might, with the utmost facility, be referred to. For this purpose two things would be required—1st. The construction of an archaeological map, which would grow in completeness with the years; and 2nd, the publication of an annual register, properly classified and indexed with a record of all finds, succinctly described and illustrated; and brief notices of important communications. These two aims might not seem very ambitious, but it would be found that they were very comprehensive, and they had at the same time that character of definiteness which was essential in all co-operative work likely to be useful. He proposed that every archaeological society in Scotland should help towards the accomplishment of those objects by the formation of a central executive committee. After discussion, the council was instructed to communicate with the Society of Antiquaries and other archaeological societies of Scotland, with a view to united action for the objects and on the lines indicated in Mr. Honeyman's paper.

The first contract in connection with the erection of citadel buildings in Westgate-road, Newcastle-on-Tyne, for the Salvation Army, has just been let to Messrs. Middlemiss Brothers, of the same town, for £3,125. The block comprises a large hall, seating 3,000 persons, divisional headquarters, shop, and other useful appurtenances. Total outlay will be about £8,500. Mr. J. Williams Dunford, of 101, Queen Victoria-street, London, E.C., is the architect.

The Corporation of Bristol having decided to substitute wood paving for granite in two streets traversed by tram-lines. The Tramway Company objected, and applied for an injunction. The matter was argued before Justices Denman and Vaughan Williams, who on Saturday announced their decision. The latter judge was in favour of the Corporation, but withdrew his judgment, as Mr. Justice Denman was of the opposite opinion. An injunction was granted, but it was intimated that the Corporation would appeal.

## TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

## TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.). To India (via Brindisi), £1 10s. 4d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

## ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

## SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING for TWENTY-FOUR WORDS, and Sixpence for every eight words after. All Situation Advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page advertisements and alterations in serial advertisements must reach the office by Tuesday Morning to secure insertion.

## NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XLII., XLVI., XLIX., LI., LII., LIII., LVI., and LVII. may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—E. and Son.—W. and Co.—J. B.—S. of A.—C. and F.

W. D. (1. They are republished by Batsford, 52, High Holborn. 2. We do not know.)

## "BUILDING NEWS" DESIGNING CLUB.

## FIFTH LIST OF SUBJECTS.

**SUBJECT F.**—A row of five cottages, the centre one to be a grocer's general shop. Each house to be on two floors, and to comprise living-room, 168ft. superficial area; kitchen 144 superficial area; scullery, w.c., pantry, tool-house, and coal place (the shop to the central house to be provided extra to this accommodation), three bedrooms and store cupboard to each house on first floor, separate and large wash-house for general use to the rear. The building to face a village street, and have frontage set back from public footway 14ft. Back way to cottages from either end of row. Style left to competitors. Material, stone, or walls with tile-hanging above, optional; roof covered with tiles, scale 8ft. to the inch. Sufficient drawings to show design, including sketch.

**DRAWINGS RECEIVED.**—"North Star," "Fiddler," "Coombe," "X. Y. Z." in a circle, "K. W. T.," "Serpa," "Nightlight," "Y." in a circle, "Wallaby."

## Correspondence.

## THE ARCHITECTS' REGISTRATION BILL.

## To the Editor of the BUILDING NEWS.

SIR,—Allow me to inform your readers that this Bill was brought into the House of Commons and read a first time on the 13th inst., and is expected to reach its second reading on the 19th March. Its provisions are precisely similar to those of the one submitted last year, but which, owing to the time given to the various architectural bodies to consider its clauses, was not presented till late in the session, and hence did not reach its second reading. The most serious objection raised to the original Bill, introduced by the late Col. Duncan, was that civil engineers and surveyors were included in its scope. The objection now taken in the same quarter is founded on the fact that engineers and surveyors (with the important exception of those holding public appointments) are excluded from its pro-

visions. The inconsistency of our opponents can surely be carried no further.

There is but little time between this and the second reading; but if the three hundred architects who gave their written approval of the principles involved some four years ago, and if the three hundred and fifty members of the Institute who signed petitions in favour of the Bill, and who have otherwise shown sympathy with its objects, will now bestir themselves, and invite their respective representatives in Parliament to support the Bill, they may do much to further its success. I ask all, therefore, to do this much at once, and not delay until it be too late. It must not be inferred that only 350 members of the Institute are in favour of the measure. I know of very many more myself, and believe the number may safely be doubled; but the majority have been waiting in vain for the Institute to move in the matter. If any of these still feel that they cannot support the present Bill let them at least make an effort to press forward their views at the Institute, and they will find that they have more support than they think for. Of those who have petitioned in favour, about 150 are Fellows, and the remainder Associates; 71 have obtained admission by examination (four in the class of proficiency), 23 have qualified for district surveyorships, and 15 have obtained travelling studentships, or are prizemen or medallists, and seven have been, or are, presidents of societies.

Let it not be forgotten that at the last Congress of the Institute a resolution in favour of the measure was lost by the casting vote of the chairman only; that a committee was formed to consider the subject, and a report drawn up, but never published. The Institute has admitted the principle we are contending for, by imposing a test for membership of its own body. All we ask is that that test be extended to all hereafter entering the profession. This is only fair towards those who do voluntarily offer themselves for examination, and until it be made compulsory upon all the Institute can only occupy the position of a more or less select club, instead of becoming, as it ought, the representative body of the profession.

The feeling in favour of such legislation is making rapid strides, not only in England, but in France, where four national congresses have approved of the principle; in Australia, where it is proposed to make it a Government measure; in the United States, where efforts in the same direction are being made; and in Canada. In regard to the latter country, the Secretary of the Ontario Association writes to me that "93 percent. of the whole profession in the province are in sympathy with the movement, with less than 1 per cent. in opposition, the view of the remaining 6 per cent. being unknown to us." Their president also, in addressing the annual convention, said: "There is hardly an architect of note practising in this province who has failed to identify himself with the movement. Our undertaking is no longer a mere Utopian fancy. We have accomplished as much in twelve or fifteen months as our brethren in the Mother Country have in more than as many years." Their Bill is now, I believe, before the Legislative Assembly.

With architects in France, America, Australia, and Canada I am in frequent correspondence. From Chicago a leading and well-known architect writes:—"Persevere in your noble work, for if the Registration Bill becomes law, I am confident the science of architecture will receive such an impetus for good that the rising generation will cherish your memory for ever."

From the Ontario Association of Architects I have received the following resolution:—"That the thanks of this association are due to Mr. Hugh Roumieu Gough for the courteous and valuable assistance he has rendered us; that we honour him for the glorious fight he is making in the cause of Registration, and heartily wish him the fullest success in the future."

I give these to show that the movement is not the mere whim of a few, as some of our opponents endeavour to believe, but that, on the other hand, it has a world-wide interest.

With these and other like expressions of sympathy and approval from abroad, I feel that Registrationists at home may well take courage and continue to persevere in their efforts until success is attained.—I am, &c.,

HUGH ROUMIEU GOUGH.

12, Carlton Chambers, Regent-street, S.W.  
Feb. 24.

## IS NOT REGISTRATION DESIRABLE?

SIR,—Your correspondents, "X." and "F. N. K.," by sending the extracts of advertisements for insertion in your journal, probably imagine that they have done something for the registration cause; but I am at a loss to understand the necessity of periodically drawing attention to such exhibitions. Surely no good and true member of the profession would envy the advertisers any business they might derive from their venture; but whether the course adopted by them is exemplary or otherwise remains an open question.

Who's to "bell the cat," when the profession teems with persons who arrogate to themselves the titles of "architect," or "architect and surveyor," and do not scruple to use any means, foul or fair (more often the former), to obtain commissions which their fellow practitioners have a right to expect from recognised clients?

I do not deny that the profession suffers from the ravages made by auctioneers, builders, and others, who either *do* plans or keep a cheap clerk for that purpose. Be that as it may, there are many builders—aye, and builders' clerks—whose skill in construction and details is of a higher order than many so-called architects. Again, I could quote illustrations of work by architects and surveyors which show such utter ignorance of the principles of design and construction as to make one blush for shame, and yet they make a good living, while their more competent brethren struggle to make both ends meet.

It is a 19th-century scandal that true merit is so frequently unrecognised and relegated to obscurity, while cheeky ignorance and incompetence, assisted by "a friend at court," flourish triumphantly.

The question for registrationists is how to effectually remedy this, not how shall we combine to fix a scale of charges for our work? else let us form a "professions" union, and disguise the fact no longer.—I am, &c.,

Feb. 24. SEMPER PARATUS.

SIR,—In my opinion, registration is desirable, and in classes. Firstly, a class of thoroughly qualified gentlemen (in every sense of the word) who have passed the examination which, no doubt, the R.I.B.A. officials are capable of conducting as expert architects. So is the class of M.I.C.E., that of A.I.C.E., that of A.S.I. (whose examination is now advertised in your paper), and others.

The class of expert architect seems to be defined by the R.I.B.A. as a gentleman of high general education (the higher the better, University if possible), having a general knowledge of building materials, of the labour necessary to fit them to their several uses, of the natural laws of their existence, of the statutory laws relating to property, tenure, Contract and Building Acts, and of the local by-laws (sanitary and building) in his particular locality, with ability as a modeller, specification writer, and draughtsman, to put in form intelligent to workmen his special knowledge of construction and design, which it is most important he should acquire in one or more styles of architecture, and of his possession of which he has convinced his client by his drawings, sketches, and general description, to which add some knowledge of "cost of production."

It is to the "cost of production" of such "expert architects" I wish to call your attention. Assuming the School Board "standard" to be necessary for all English boys, and to be reached by the "raw material" of which all "Britishers" are composed, we have, in quantity surveyor's vocabulary:—

Extra only to converting a School Board boy into a University degree gentleman (inclusive of books, food, and petty expenses), allowing for loss of time during education period.

Expense of pupilage, inclusive of premium and all, as last.

Cost of additional time as improver over actual earnings.

Cost of tours for professional experience during the last two periods.

Credit professional earnings during the remainder of active life.

My object in calling attention to these facts is that for architecture to pay its practitioner must have a very large clientage, and that there is very small chance of the ordinary pupil obtaining

such a clientage; nor (as the R.I.B.A. admit) is 5 per cent. remunerative on small jobs.

It seems to me that one of two things must occur: either small jobs must go on without the qualified architect, or he must work at unremunerative commission. If he is prepared to do the latter, let it be generally known; but if he is not, why does he grumble at others who will?

Again, would it not be possible to have a "lower branch" of architects, such as the country surgeon is to the consulting physician, or the registered chemist to the country surgeon, but qualified men of their class.

Then we come to clerk of works. We have men in large estate offices (at royal castles, at the cathedrals, and similar places), and men under our great architects; but this title, like architect, is assumable by anyone; it is held by many clever and honourable men, and by lots of dishonest duffers. The question of their "status" greatly affects that of architects, and if one takes the Royal Engineers as a copy, it almost seems as if a system of "rank" was required, men capable of small jobs and men expert in specialities. How could this be made workable?

No doubt the whole question of "qualification" of men engaged in supervision of work, whether as engineers, architects, clerks of works, &c., is one of the questions of the day. But it must be borne in mind that in small places and country towns there is no room for specialists, and those who have a small amount to expend should not be hindered by vexatious professional quibbles; yet a man who could not pass the higher examination might be found who could supervise small works cheaply, as the uncommissioned R.E., probably under a more qualified man. What is wanted, is on large or small works there should be qualified supervision; but on small works, say under a hundred pounds, this cannot be remuneratively given by the architect on present terms.

What would the proposers of registration recommend for these works if all works have to be under supervision?

Whilst leaving the central idea to more favoured hands, will you please give me room to plead the cause of, those like myself, on the

CHECKERED BORDER.

## A NEWSPAPER DESK.

SIR,—The desk for newspapers shown in last issue is not a good form, though commonly used; when the wood shrinks it gets rickety and soon

falls to pieces. I speak from experience, having seen a similar one under repair. It should be well braced from end to end, as it is often dragged about the floor while the latter is being washed. I inclose sketch of another which I think far stronger—at all events, it has not come to grief as yet.—I am, &c.,

JAS. SPARROW.

Reading.

Mr. Alfred Ivey, surveyor, of Clapham, while taking measurements last week for the rebuilding of the premises recently destroyed by fire in Aldermanbury, fell down the lift, sustaining fatal injuries.

## Intercommunication.

## QUESTIONS.

[10233.]—**Who is Responsible?**—In a competition for finishing a church in the south of Ireland a lithographed sheet of drawings was supplied to each of the competitors, in which four existing piers were scaled and figured 35ft. 9in. high. In the printed instructions issued to competitors there is a clause as follows:—"It would be well for intending competitors to visit the church and satisfy themselves on all points." In another paragraph farther on it is stated that the piers are of different heights, but that the pier figured 35ft. 9in. is the lowest. The successful architect prepared his drawings, showing the existing work according to the lithographs, and the new work coloured blue. A contract was taken for a sum within the amount stated in conditions. When the scaffolding was erected, and the existing piers measured it was found that they were nearly 8ft. lower than was shown in lithos (the lithographs were prepared by an architect who acted as umpire and adviser to the committee). The contractor claims payment for the additional work; but the committee maintain that the selected architect should have measured those piers before he sent in his drawings for competition. The architect, on the other hand, throws the blame on the umpire who prepared the lithographs. The conditions were rigid as to cost, and if his drawings contained more masonry than was shown by the other competitors he would be placed at a great disadvantage, and also that it was not just to expect him to go to the expense of providing ladders and men, and losing a day measuring the work, for the time was extremely limited—that is, supposing he had a doubt as to the accuracy of the measurement of the piers; but he had no reason to doubt their accuracy. Who should be held responsible for the mistake?—SUBSCRIBER.

[10234.]—**Radius of Arch.**—Will someone please give me an algebraic formula for finding the radius of an arch when the span and rise are given?—CLERK OF WORKS.

[10235.]—**School Plans.**—What areas per child are absolute in alterations to denominational schools where grant is requested? What for same where no Government regulations are compulsory? Have plans to be approved by any authority (except the local) when additions to national schools are contemplated? If so, name authority, and if regulations are to be had.—DOUBT.

[10236.]—**Damp Flags.**—I have a cottage property with stone flagged kitchens, which in some parts have the appearance of being damp; but I am of opinion that it is not caused by dampness, as one portion of a flag will have this appearance, and the other portion appears quite dry. Is there any remedy or application that will remove the damp appearance?—JOHN YATES.

[10237.]—**Moment of Inertia.**—Will someone explain fully and simply the meaning of moment of inertia, and show how to obtain the B.W. of any section (say an angle or tee-iron) by this method? A sketch of a good turned joint for connecting a series of C.I. columns would also be very acceptable.—READER.

[10238.]—**Boiler.**—Could any of your readers favour me with their experienced advice in the following case? A firm of contractors have agreed to do certain repairs to a house, and, among other things, it is specified they are to "examine, clean out, and put in proper working order the large boiler" in cellar. The contractors cleaned out and endeavoured to put the boiler in proper working order; but after testing it, the boiler was found to be worn out and perfectly useless for the purpose, so that a new boiler became necessary. Who is liable for cost of boiler and fixing?—ARCHITECT.

[10239.]—**Late Work in Yorks.**—Would some of your readers kindly give me a short list of 16th or 17th-century work in the north of Yorkshire which is worth sketching during a summer's tour?—PENCIL.

## REPLIES.

[10222.]—**Billiard-room Floor.**—To carry a billiard table, increase of rigidity is of far greater consequence than increase of strength, and I have tongued floors in the manner following:—Suppose the room to be 24 by 18, and the joists to be 12in. deep, give the last joist at each end of the room a bearing on the wall by corbel or set-off, and run a rod (say  $\frac{1}{2}$  iron) under each line of legs of the table from end to end of the room jointed in three lengths. The length of rod at each end will be about 7ft., and will be run in a slanting direction from the top of the end joist (where it will be turned over or bolted) through the intermediates down to the bottom of the joist, where the centre length meets it. This centre length may be a bar  $1\frac{1}{2}$  by  $\frac{3}{4}$ , and may be screwed up to the joists as well as connected with the rods. The trussing will then be effected by cutting in and driving tightly down to the top level from joist to joist a row of straight bridgings in a line over the rods.—WILLIAM WHITE, F.S.A.

[10224.]—**Sound.**—Some years ago I was troubled with noise from an overhead schoolroom. I worked up the theory and practice of the subject, and considered silicate cotton or slag wool, though evidently good, somewhat expensive. A happy inspiration induced me to try the moss litter I use in my stables, which costs about one-sixth the price of slag wool; a hundredweight also has the advantage of going much further, and, like it, no insects or vermin harbour in it. The result was eminently satisfactory. Since then I have used it successfully between match-boarded partitions, and for the latter purpose I believe it has no equal, for being so light, it exerts very slight thrust on the boards. I recommended it to the company I buy my litter of, and I believe they now advertise it for the purpose. A rough estimate for one square would be 1 to 2 cwt. —E. H. BELLARS, Christchurch, Southampton.

[10224.]—**Sound.**—To fill in the sawdust or deafening material will be the better plan to prevent the transmission of sound; as a timber-framed partition, match-boarded, is only partly hollow, the sound vibrations would easily pass through the studding. If an uninterrupted air-space existed, it would have some value in deadening the sound.—G. H. G.

[10225.]—**Echo.**—Try to confine the space over the speaker's chair by constructing a temporary ceiling of canvas on frame. The height is too great, and I should recommend the construction of a ceiling suspended from roof as the only plan likely to be a success.—G. H. G.

[10225.]—**Echo.**—No particulars are given as to whether the floor is boarded or the rafters lined with boarding or plastered, or the rafters shown. Probably there would be no echo if the room were ceiled across at the level of the wall-plate, with that proportionate height of wall. Perhaps an experiment might be made by suspending a tarpaulin horizontally at the platform end at that level, say over about half of the room, or laying scaffold planks across, from the effects of which some judgment might be formed as to what could or should be done.—WILLIAM WHITE, F.S.A.

[10227.]—**Natural Bed.**—The bed of stone in a joggled arch would be better placed in the direction to offer the greatest resistance to shearing. I should say perpendicular to the joints; but much depends on the form of arch. If flat, I should prefer the usual method for other reasons.—G. H. G.

### CHIPS.

We observe that in the report on agricultural implements and machines just issued by the Government of India, the hand pumps, as made by Hayward Tyler and Co., of Whitecross-street, London, for deep and shallow wells, are specially pointed out for their utility and adaptation, stress being laid on the advantages of their system as preventing pollution of the water in the well.

The town council of Longton, Staffs, discussed at length, on Friday, which they should adopt of two plans for the erection of a pavilion in the Queen's Park, proposed by Mr. J. Taylor. A committee recommended the selection of the larger scheme having wings, the additional cost of which was £1,752; but the council decided to adopt the less expensive design.

A committee of the Liverpool city council have recommended that body to accept Mr. P. H. Rathbone's offer to bear the expense of the completion with sculpture by Mr. Stirling Lee of the vacant panels in St. George's Hall. It will be remembered that after two panels had been filled by Mr. Lee, objections were raised to a nude female figure, and the council decided not to proceed with the work.

On Friday last, Mr. G. Herbert Bayley, engineering assistant to Mr. Ar. Jacob, B.A., Mem. Inst. C.E. borough engineer and surveyor of Salford, was unanimously appointed engineering assistant to Mr. E. G. Mawbey, A.M.I.C.E., the borough surveyor of Leicester. Mr. Bayley was formerly articled pupil to Mr. Jacob.

The Erith local board, at a meeting held on Monday last, had before them five selected candidates for the office of surveyor to their town. On the voting being taken, Mr. T. W. Franks, assistant surveyor, West Bromwich, and Mr. S. Toulson, assistant surveyor, Plumstead, received an equal number of votes, the latter being appointed by the casting vote of the chairman. There were 67 applicants.

The names of the following builders are included in the list of receiving orders in Tuesday's *Gazette*:—S. Horlock, Manor Park, Essex; Thomas Aldridge, Lewisham; and James Snelling, Pontypridd.

At a meeting held at the Council House, Birmingham, it was decided to take steps for the restoration and repair of St. Mark's Church in that city, one of three built fifty years ago. The architect for the restoration is Mr. J. A. Chatwin, and the estimated sum required is between £2,000 and £3,000.

On Thursday, the 20th inst., Mr. J. T. Harrison, M.Inst. C.E., an inspector of the Local Government Board, held an inquiry in the Town Hall, Crewe, with respect to the application of the town council to borrow £500 for works of street improvement and sewerage. The money is intended to be spent in the making of a relief sewer along Hall-o'-Shaw-street, at a cost of £150, and the re-paving of Cemetery-road and Market-street, which will cost £350. The borough surveyor, Mr. Geo. Eaton Shore, produced the plans and specifications for the work, and explained the schemes. There was no opposition.

Two years ago the condition of the Cathedral of Seville, once a mosque, excited great anxiety. A pillar and part of an arch in the nave fell, and fears were entertained that the whole building might collapse. The danger of further mischief has been averted. The fallen pillar and arch are being replaced, and other extensive repairs and restorations are being carried out. Especially the entrance known as the Portal San Cristobal, which was never finished, is being now renovated and completed.

A new schoolroom adjoining the Congregational chapel at Watford was opened last week. It is Gothic in style, and in harmony with the chapel, being built of red brick; it is seated for 150 persons, and has been built by Mr. W. Judge.

### WATER SUPPLY AND SANITARY MATTERS.

**OUNDLE SEWERAGE.**—The Commissioners of Oundle held a special meeting last week to consider plans submitted by Mr. W. H. Radford, C.E., of Nottingham, for the sewage disposal of the town. The engineer explained that he proposed to purify the sewage in duplicate precipitation and filtration tanks, the chemicals and filtering medium being supplied by the International Sewage Purification Company. The sewage mud would be pumped on to air-drying pits by means of a small circular windmill. The whole of the town sewage would be delivered to this site by various new pipe sewers, the sewage of one low-lying locality being pumped into a high-level sewer by a small compressed air-pump placed under the street, and supplied with compressed air through a pipe from the new water-works engine. The Commissioners decided to carry out the scheme in its entirety.

**THE POLLUTION OF THE RIVER AIRE.**—A conference was held at the Leeds Town Hall on Monday between members of the Leeds Rivers Pollution Committee of that corporation and a number of members of the Bradford Town Council upon the question of what steps can be taken to prevent the pollution of the Aire. The conference, which was private, occupied about two hours, and the various questions at issue between the two corporations were discussed. An agreement was arrived at, to the effect that the most effectual mode of promoting the purification of the Aire would be by the establishment of a Conservancy Board. It was concluded that the town clerks of Leeds and Bradford should write a joint letter to the West Riding County Council and the local authorities along the watershed of the river Aire, asking them to co-operate together in an application to the Local Government Board, under the Act of 1888, to constitute a joint committee to carry into effect the objects of the conference.

### LEGAL INTELLIGENCE.

**IMPORTANT TO ARCHITECTS AND SUB-CONTRACTORS.**—SMITH AND SONS V. KIRK AND RANDALL.—At the Brompton County Court on Tuesday last, before His Honour Judge Stoner, this case was heard, which has considerable interest for architects, as it raises the point whether after an architect has ordered special extras of a make detailed by him and the amount has been included in the additional account at the end of the job, the general contractor can refuse payment to the tradesman on the ground that he did not order the goods. In this case the plaintiffs, Charles Smith and Sons, locksmiths, Birmingham, sued Kirk and Randall, contractors, Woolwich, for £49 5s. 6d. as payment of a balance for extra locks supplied under an order by the architect, Mr. Thomas Verity, to defendants as contractors for the Kensington Public Baths. The defendants pleaded that while they did agree with plaintiffs to supply certain locks, and duly paid for them, they gave no orders for extras, nor did they receive payment for them from the Bath Commissioners. Mr. Rose Innes appeared for plaintiffs, and Mr. Raven for defendants. Mr. Charles Smith deposed that his firm were sub-contractors for locks and other ironmongery in the contract for the Kensington Baths taken by defendants. The plaintiffs were paid on that sub contract £97 10s. 3d., and an account was sent in for extras to Mr. Verity as the architect in the ordinary course of business. Mr. Verity certified that £49 5s. 6d. was due to the plaintiffs. As this sum was included in the final certificate on which payment was made to defendants, plaintiffs' firm applied for the balance, but never received it. Cross-examined: Defendants wished to give the contract to another firm. Plaintiffs had an order for the work, not from defendants, but from Mr. Verity. Plaintiffs never sent in an account to the defendants, having sent it in to the architect. Mr. T. Verity, F.R.I.B.A., proved that additional locks, the subject of this action, were ordered by the Bath Commissioners, and were supplied by plaintiffs, to his satisfaction. Witness examined them with the clerk of works, and passed the account for payment. Mr. F. H. A. Hardcastle, quantity surveyor, deposed that he measured up the work for the architect with Mr. Batstone, surveyor for Messrs. Kirk and Randall, and the bill jointly prepared by them, including the extras in question, was produced before the commissioners prior to payment of final certificates. No objection was raised to the payment of this item, which was duly included in the final account. Mr. Verity, recalled, said that none of the items included in the additions side of the account was repudiated by the defendants. Joseph Randall, one of the defendants, stated that he knew nothing of the account now sued for until some weeks after the transaction was closed. Witness declined at the final settlement, which ended in a compromise, to recognise the accounts prepared by the joint surveyors, Batstone and Hardcastle, and submitted a fresh set of accounts to the Commissioners. W. H. Murlis, one of the Bath Commissioners, deposed that at a meeting of the board for final settlement,

when a compromise was arrived at under which defendants accepted £2,500 in settlement of all charges, he heard no reference made to plaintiffs' claim for extras. His Honour, in giving judgment, said that if the defendants, as contractors, knew nothing of the sub-contractor's claim, it was their business to make inquiries, it being their duty to protect the sub-contractor. Constructively, they knew of all the items in the account which Batstone, as their surveyor, had assisted in preparing. It being, therefore, defendants' omission, he should give judgment for plaintiffs with costs.

**RE T. QUINN, M.P.**—A first meeting of creditors was held on Tuesday before Mr. Chapman, assistant-receiver, under the failure of Mr. Thomas Quinn, M.P. for Kilkenny, and of the Estate Office, Popham-street, Islington, builder and contractor. The statement of affairs showed unsecured debts £9,079, and debts fully secured £66,638, with assets estimated at £919. The debtor commenced business about 26 years ago with a small capital. In 1870 he was adjudged bankrupt, under which proceedings a composition arrangement was approved, and the adjudication annulled. The composition, however, was not paid, and in July, 1872, he was again adjudged bankrupt, under which proceedings his discharge was granted in January, 1886. No dividend appears to have been paid. He attributes his present failure and deficiency to his inability to sell his mortgaged properties, and to depreciation in the value of the same as now estimated for realisation; also to heavy law costs and other expenses in connection with his properties and business, and partly to his household and personal and medical expenses (about £800 per annum). The securities held by creditors, treated as fully secured, consist chiefly of mortgages on blocks of artisans' or industrial dwellings built by the debtor at Waterloo-road, Islington, and Bethnal-green. The debtor offered a composition of 5s. in the pound, payable in two instalments at fourteen days and six months from the date of approval. A lively discussion followed, but the proposal was entertained by the necessary majority of creditors.

### CHIPS.

On Friday an interesting gathering took place at the Stalls Workshops on the Longleat Estate, near Warminster. It was to celebrate the 38th wedding day of Mr. and Mrs. Buckenham, the coming of age of their eldest son, and to bid farewell to Mr. Buckingham on his resigning his position as clerk of the works to the Longleat Estate, a post which he has held for twenty-seven years. Mr. Buckingham invited the workmen at the Stalls to a supper. Mr. J. Sims (foreman) presided, and presented a marble clock, subscribed for by the workmen on the estate, to Mr. Buckingham, who suitably replied. A concert followed, in which Mr. Buckingham's sons and daughters took part.

The improvement committee of Newcastle-on-Tyne have decided to carry out a large number of drainage and paving works in various parts of the city, at an estimated cost of £28,140.

The Milnrow local board have just erected a handsome building of stone as their offices and fire station, and a committee have succeeded in collecting a sufficient sum to erect a tower and clock on the offices, in memory of the late John Bright. The clock has been specially made by Messrs. J. B. Joyce and Co., and includes all the latest improvements. There are four illuminated dials, and the bell can be heard for several miles.

Alterations have been made to the New River Company's premises, Finsbury Park, embracing the ventilation, which is now carried out on the Boyle system.

The Salvation Army has just purchased a very prominent site in Cowgate, Peterborough, and intend erecting on the same a large citadel capable of accommodating 1,000 persons, and two large shops. Mr. James Wenlock, builder, Peterborough, has secured the first contract, but the main portion has not yet been tendered for. The architect is Mr. J. Williams Dunford, of 101, Queen Victoria-street, London, E.C. The scheme will cost about £5,000.

The Departments of Antiquities in the British Museum have just been enriched by the purchase of a portion of the Earl of Carlisle's collections from Castle Howard, including a Late Greek vase, bearing the signature of its painter, Python, and representing the interrupted burning of Alcmena, who has been placed on the pyre by her husband, Amphitryon, and in answer to whose prayer Zeus extinguishes the flames; and also two Roman phalerae, consisting of busts of boys carved in bluish grey chalcidony. Among the Mediaeval and Renaissance gems acquired from the same collection the two most important are a contemporary portrait of Lorenzo de Medici, and another portrait supposed to be that of Louis II.

Professor Carl Bloch, the eminent Danish painter, died on Saturday night, at the age of fifty-six.

## Our Office Table.

THE profit-sharing scheme recently proposed by Messrs. Peto Brothers, under which they offered to give one quarter of the whole net profits to the men employed on the Cane Hill Asylum extension works, has been criticised by the London United Building Trades Committee. Special exception is taken by the committee to the following provisions:—“(a) All right to participate in the profit will be forfeited by any who earn less than a total amount of £5 in wages on the contract. (b) All share of profit will be forfeited by any who may individually, or in combination, do anything tending to diminish the profits on the contract by neglecting their duties, misconducting themselves, wasting their time, or by joining any strike for shorter hours, or for wages above the existing recognised rate of wages, whether the strike be general or otherwise. (c) All profit will be forfeited by anyone who may do anything tending to damage the character of the firm for good and honest work; the shares of any men so forfeiting their claims to be added to the shares of the others.” The committee “appeal to the workmen to withhold their co-operation until Messrs. Peto Brothers have shown that full confidence in their workmen which they evidently have in their own self-assurance and importance.” The committee further asked Messrs. Peto Brothers either to modify the conditions or consent to the withdrawal of the scheme; but they have replied that it is for the workmen asked to accept or reject the offer, and that it is not in their power to withdraw it without the consent of the men.

THE Trustees of the British Institution Scholarship Fund will proceed in July next to the election of five scholars—one in architecture, two in painting, one in sculpture, and one in engraving. The scholarships are of the value of £50, and are tenable for two years. Candidates must be between seventeen and twenty-three years of age inclusive; and, subject to this limitation, the scholarship in architecture is open to all art students who have obtained gold medals or scholarships or money prizes of the minimum value of £10 in any art school in the United Kingdom, and who submit for examination the following works:—(1) A measured drawing of a portion of an existing building; (2) a freehand shaded drawing of a capital, both on a half-imperial sheet of paper; (3) a design for a science and art museum in a provincial town. The drawings are to consist of plan and elevation both to a scale of  $\frac{1}{2}$  in. to a foot, and of a section to a scale of  $\frac{1}{4}$  in. to a foot. Further particulars and the regulations to be observed can be obtained on application (by letter only, and inclosing a stamped, directed envelope) to the Trustees, British Institution Scholarship Fund, 19, York Buildings, Adelphi, W.C.

THE Royal Society of Painter-Etchers elected on Tuesday night the following gentlemen as Associates:—Messrs. A. W. Bayes, W. Boucher, C. F. Robinson, and F. S. Walker. The Society announce that, their object being not merely the restoration of original etching, but the re-infusion into all forms of the engraver's art of the painter-like qualities which to a great extent it has lost, it has been determined to include in each annual exhibition of the works of its fellows a few typical examples by one or other of the great masters of etching, beginning at the forthcoming exhibition, which opens to the public on Monday next, March 3, with those of Rembrandt.

AMONGST recent developments of warming is “power heating” for large buildings. The requirements are boilers, a power fan to force the air through steam coils, and ducts to distribute the heated air-currents through the building. These ducts are proportioned to the several rooms. From the coil-chamber a brick tunnel of sufficient size is taken to the building, a rather smaller square pipe distributes the currents right and left, each room having its separate branch-pipe, and exhaust flues leading off to the outer air. These are considered sufficient for ventilation. To regulate the amount of air to each room dampers are placed below the registers. The ducts are proportioned to each room, and upon the proper size of these and the means of adjusting the amount of air to each, depends the success of the system. Mr. W. L. B. Jenney, architect, of Chicago, has applied the plan to the Normal

School at Terre Haute, a plan of which appears in the *Engineering and Building Record*.

AN Exhibition of Art Brasswork will be opened in London on the 20th of May, under the auspices of the Company of Armourers and Braziers. The exhibition will take place in the hall of the Company, 81, Coleman-street. Craftsmen's prizes are offered for ecclesiastical and domestic articles in brass and bronze, and metals with brass combined; also for modern armour, breastplates, and blades, as well as for designs and specimens of work in casting, brazing, hammered hollow-ware, repoussé work, engraving, applied ornament, niello, and damascening. There are also special prizes for apprentices, and for the joint work of designers and craftsmen.

ANOTHER effort, says the *New York Evening Post*, is being made to utilise the power of the Niagara River above the falls by means of a main tunnel two and a half miles long, with certain cross tunnels, and a large sum has been already subscribed. It is thought that if thirty mills are built and supplied with 500H.P. each, the investment would pay 5 per cent. The estimated cost is 2,250,000 dollars. It is strange more has not been done to utilise the power of the Falls itself, and many feasible schemes have fallen through.

ON Friday evening last Mr. Harland Lemon, the popular humorous reciter, gave an evening's recitals at the Ventnor Hall, Hove, to the whole of the staff and workmen, with their wives and families, of the firm of Mr. J. T. Chappell, builder, London, a most enjoyable evening being spent; Mr. Winter, the manager, represented the head of the firm. The programme consisted of a selection of humorous pieces, which were given in Mr. Lemon's inimitable style, and created roars of laughter. The principal pieces recited were “The Eatanswill Election,” “One More: the Tale of an Old Salt,” admirably rendered; “How Bill Adams Won the Battle of Waterloo,” being a new account of a great historical event; “The Three Parsons,” “One Niche the Highest” (by desire), this selection proving Mr. Lemon to be not only a humorous, but also a dramatic, reciter of a very high order; Sketchley's “Mrs. Brown's Vote Solicited,” and “Rubinstein's Piano”—the intense power and masterly description displayed in the delivery of the latter drew forth rapturous applause.

### CHIPS.

The fourth of the present series of free lectures at Carpenters' Hall was given on Wednesday evening by Professor Armstrong, who took as his subject “The Domestic Fireplace.”

The formal opening of Trinity-road Baptist Church Schools, Upper Tooting, S.W., after enlargement, took place on the 11th inst. A special feature in connection with the alterations is the provision of a church parlour, cosily furnished with every requisite for comfort, over a part of the school-room, which is intended to be used for small social gatherings in connection with the church. The alterations and additions were carried out by Mr. W. Johnson, of Wandsworth Common, at a cost of about £800, under the superintendence of the architect, Mr. E. Elton Hawkins, 19, York-buildings, Adelphi, W.C.

The Ashley-street board school, Carlisle, is nearing completion, and is being warmed and ventilated throughout by means of Shorland's patent warm air ventilating Manchester grates, and open fireplace Manchester stoves, the same being supplied by Mr. E. H. Shorland, of Manchester.

In the ancient parish church of Stockland, near Honiton, which was reseat and restored in 1888 under the direction of Mr. Edmund Ferrey, has just been placed a new pulpit, subscribed for by the parishioners, and designed by the same architect. In form it is octagonal, the superstructure of oak, with ornamental open panels and carved cornice, the pedestal being of the red Bishops Lydeard stone, with blue Keinton steps.

The foundation-stone of the new church of St. Hilda, at Hedgefield, Co. Durham, was laid on Saturday afternoon. The church will occupy a beautiful site overlooking the river Tyne, and with distant views of Heddon-on-the-Wall, Throckley, Newburn, and Newcastle on the opposite bank of the river. The architects have adopted the Cornish type of village church, characterised by low, massive western towers, low side walls, and barrel-vaulted ceilings. The accommodation is for 273 persons. The work is being carried out by Mr. Alexander Pringle, of Gateshead, from the designs and under the superintendence of Messrs. Oliver and Leeson, of Newcastle.

### MEETINGS FOR THE ENSUING WEEK.

- MONDAY.—Royal Institute of British Architects. Discussion on J. Slater's paper, “Building Regulations,” 8 p.m.  
Clerks of Works' Association. “Light-house Construction,” by T. Edmond. 8 p.m.  
Leeds and Yorkshire Architectural Society. “The Revival of Applied Art,” by Mervin Macartney.  
Liverpool Architectural Society. “The Decorative Panels of St. George's Hall,” by J. M. Hay.  
TUESDAY.—Institution of Civil Engineers. “The Hawkesbury Bridge, N.S.W.,” by C. O. Burge; “The Dufferin Bridge, Benares,” by F. T. G. Walton; and “The New Blackfriars Bridge, London, Chatham, and Dover Railway,” by C. E. W. Crutwell. 8 p.m.  
Manchester Architectural Association. “Notes in Holland and Belgium,” by T. Chadwick.  
Glasgow Architectural Association. Annual meeting. 8 p.m.  
WEDNESDAY.—Carpenters' Hall Free Lectures. “The Forth Bridge,” by Prof. A. B. W. Kennedy, F.R.S. 8 p.m.  
Society of Arts. “Recent Progress in British Watch and Clock-Making,” by Julian Trippin. 8 p.m.  
Civil and Mechanical Engineers' Society. “Fresco Cement,” by Edwin Lucas. 7 p.m.  
THURSDAY.—Royal Archaeological Institute. “Anglo-Saxon Ornament compared with Anglo-Saxon MSS.,” by J. P. Harrison; “A Brass at Newcastle,” by A. Oliver. 4 p.m.  
Edinburgh Architectural Association. Paper by J. Kinross. 8 p.m.  
FRIDAY.—Royal Institution. “Electrical Relations of the Brain and Spinal Cord,” by F. Gotch. 9 p.m.  
SATURDAY.—Society of Arts. “The Atmosphere,” by Prof. Vivian Lewes. 3 p.m.

## Trade News.

### WAGES MOVEMENTS.

EDINBURGH JOINERS.—At a large meeting of the Edinburgh and Leith Operative Joiners held in St. Mary-street Hall on Friday night to hear the employers' reply to the demand for an advance of  $\frac{1}{2}$ d. per hour, a letter was read from the secretary of the Masters' Association, expressing their willingness to meet the men half-way. The meeting heard reports from the various shops with a view of ascertaining the position of affairs. The reports submitted showed that 42 masters, employing 811 men, had conceded the demand in full, while 12, with 255 men, had offered  $\frac{1}{2}$ d. increase. This report was considered highly satisfactory, and it was unanimously resolved to continue the agitation.

NEWCASTLE-ON-TYNE.—The bricklayers' labourers of Newcastle and Gateshead sent notices for an advance of  $\frac{1}{2}$ d. per hour all round, but the masters have not so far responded favourably. The notices will expire to-morrow (Saturday), when, if the advance is not granted, the men will come out on strike.

NORTH BERWICK.—The joiners here who went on strike for an advance of  $\frac{1}{2}$ d. per hour resumed work on Tuesday, the masters having conceded the rise.

PAISLEY.—At a mass meeting of joiners, held in the Globe Temperance Hall, Paisley, it was agreed to ask an increase of wages of  $\frac{1}{2}$ d. per hour, and, if it were not conceded, to come out on strike on 17th March.

THE YORKSHIRE POTTERY TRADE.—A meeting of the Association of Earthenware Manufacturers of Yorkshire was held at Pontefract on Tuesday. With the exception of one firm, the whole of the manufacturers of the Castleford, Ferrybridge, Swinton, and Rotherham districts were present. A discussion took place as to the demand of the men for a return of the 10 per cent. on working prices conceded to the employers in 1884-5, and it was unanimously decided to adhere to the previous decision, not to grant the return asked for. The workmen have given notice, and will undoubtedly come out on strike. The notices expire to-day (Friday). Over 1,000 hands will be directly affected. The workmen have formed an association called “The Yorkshire Potters' Association,” and have joined the Sheffield Trades Council. The Staffordshire potters are likely to forward assistance to their Yorkshire brethren.

The new mission hall and classrooms in connection with St. Saviour's Church, Battersea Park-road, S.W., were formally opened on the 13th inst. The building, which stands immediately behind the church, comprises a hall 80ft. by 40ft., and three large classrooms. Mr. E. Elton Hawkins, of 19, York-buildings, Adelphi, W.C., was the architect, and Messrs. G. N. Street and Son, of 34, Surrey-lane, S.W., the contractors.

## CHIPS.

The town council of Leeds have received a report from Mr. T. Hewson, their waterworks engineer, stating that of the Blackmoor tunnel 1,490 yards has been bored, and the work is being trimmed by the contractor, Mr. Simpson, of Hunslet, preparatory to being lined with brickwork.

A new refuse destructor at Burslem, erected by Messrs. Manlove, Alliott, and Co., of Nottingham, for the town council, and under the direction of Mr. Sheldon, borough surveyor, was inaugurated last week.

All Saints' Church, Rockwell Green, Wellington, Somerset, was consecrated on Tuesday week by the Bishop of Bath and Wells. The church, the style of which is of the Transition period from the Early English to the Decorated, consists of a nave with clerestory, north and south aisles, chancel, north and south transepts, and a vestry adjoining the north transept. The plans include a tower, but the building of this has not been included in the first contract. The walls are built of red sandstone, lined internally with brick and Hambdon-hill stone dressings. The roofs are covered with Staffordshire tiles. The church is fitted with open benches of pitch-pine. The floors of the passages are paved with tiles, and the floors under the seats are laid with wooden blocks. The architect is Mr. J. Houghton Spencer, of Taunton. The accepted tender for the building was £2,765.

**Holloway's Ointment.**—This cooling Ointment, perseveringly rubbed upon the skin, is the most reliable remedy for overcoming all diseases of the throat and chest. Quinsy, relaxed tonsils, sore throat, swollen glands, ordinary catarrh, and bronchitis, may be arrested as soon as discovered, and every symptom banished by Holloway's simple and effective treatment.

## DOULTING FREESTONE.

**THE CHELYNCH STONE.**—The Stone from these Quarries is known as the "Weather Bed," and is of a very crystalline nature, and undoubtedly one of the most durable Stones in England.

**THE BRAMBLEDITCH STONE** is of the same crystalline nature as the Chelynych Stone, but finer in texture and more suitable for fine moulded work.

Prices, and every information given, on application to CHARLES TRASK and SONS, Doulting, Shepton Mallet, Somerset. London Agent:—Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.

## HAM HILL STONE.

The attention of Architects is specially invited to the Durability and beautiful Colour of this material.  
Quarries Well Opened; Quick Despatch Guaranteed; Stonework Delivered and Fixed Complete. Samples and Estimates Free.

Address:—

**THE HAM HILL STONE COMPANY,**  
NORTON, STOKES-UNDER-HAM, SOMERSET.

## TENDERS.

\* Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender: it adds to the value of the information.

**BANBURY.**—For the erection and completion of Salvation Army fortress in Banbury, for General Booth. Mr. J. W. Dunford, 101, Queen Victoria-street, E.C., architect and surveyor:—

Orchard and Son, Banbury ...	£975	0	0
Haywood and Son, Bedford ..	863	0	0
Ellwood and Son, Sandy ...	790	0	0
Hipwell, S., Wisbech ...	742	0	0
Jarvis, E., Banbury (accepted) ...	718	0	0

**BAYSWATER.**—For decorating, repairing, and altering 2, Orme-square, Bayswater, W., for Mr. F. H. Lenders. Mr. F. W. K. Tarte, M.S.A.:—

Giles, F., and Co., Kensington ...	£763	0	0
Johnson & Manners, Gt. Pulteney-street, W. ...	684	0	0
Vernall and Griffiths, Albany-street ...	67	0	0
Wells & Son, Red Lion-street, W.C.*	534	0	0

For drainage to the above:—

Beattie, R. P. ...	161	0	0
Dodds, W. ...	159	0	0
Wells and Son ...	134	0	0

For heating to the above:—

Keith, J., Holborn Viaduct ...	145	0	0
--------------------------------	-----	---	---

\* Accepted.

**BERMONDSEY.**—For sinking and building new brick pits, &c., at Horney-lane, Bermondsey, for Messrs. E. Ellis and Company:—

Wells, Bermondsey ...	£143	0	0
Ellis, S., Guildford ...	127	0	0

**BLACKFRIARS.**—For fitting up the premises known as the Oriental Restaurant as offices, for General Booth (branch offices of the International Headquarters). Mr. J. W. Dunford, 101, Queen Victoria-street, London, E.C., architect:—

Coxhead, F. J., Leytonstone ...	£1,711	0	0
Martin, A., Battersea ...	1,626	0	0
Castle, W. and H., Southwark ...	1,546	0	0

**CAMBORNE.**—For the erection and completion of Salvation Army fort in Camborne, for General Booth. Mr. J. W. Dunford, 101, Queen Victoria-street, E.C., architect and surveyor:—

Skewer, H., Camborne ...	£930	0	0
Julian, J., Truro ...	950	0	0
Walmesley and Eunice ...	929	0	0
Willoughby, Redruth ...	850	0	0

**CAMBSLARG, N.B.**—For the erection of twelve two-story tenements near the railway station, for Mr. A. G. Barnes Gresham:—

Mason and brickwork:—

Aitkenhead, of Coatbridge (accepted).

Joinery:—

Pasley and Rodie, Barnhead (accepted).

**CHATHAM.**—For the erection and completion of fortress, for General Booth. Mr. J. W. Dunford, 101, Queen Victoria-street, London, E.C., architect:—

Skinner, Chatham ...	£1,175	0	0
Burrows, Maidstone ...	1,005	0	0
Dupont, Colchester ...	989	0	0
Martin and Barclay, Battersea ...	975	0	0
Jarvis, E., Banbury (accepted) ...	895	0	0

**CHISWICK.**—For erecting a house and stables at Sutton Court Park, Chiswick, for Mr. J. Woodger. Messrs. Wylson and Long, architects:—

Wright, W. and F. ...	£1,370	0	0
Green, T. L. ...	3,889	0	0
Lee, H. and E. ...	3,815	0	0
Patman and Fotheringham ...	3,793	0	0
Newcomb ...	3,748	0	0
Kearley, C. F. ...	3,686	0	0
Chappell, J. T. ...	3,678	0	0
Nye, T. ...	3,661	0	0
Saunders ...	3,585	0	0
Hunt, S. ...	3,539	0	0
Leslie and Co. ...	3,537	0	0
Oldrey and Co. ...	3,489	0	0
Adamson and Son ...	3,477	0	0

**CHISWICK.**—For repairs, alterations, and additions to the Church of St. Mary Magdalene, Chiswick. Messrs. Newman and Newman, 31, Tooley-street, London Bridge, architect. Quantities by Mr. G. Fleetwood:—

	Church.	School, &c.
Roberts, L. H. & R.	£4,403	0 0
Balaam Bros. ...	4,008	0 0
Goddard & Sons ...	3,896	0 0
Hunt, J. ...	3,807	0 0
Chamberlen Bros.	3,749	0 0
Adamson & Sons...	3,579	0 0
Dorey, J. ...	3,180	0 0
These tenders include allowance for old materials.		

**COVENTRY.**—For the erection of school and class-rooms, and additions, &c., to the Wesley Chapel, Warwick-lane, Coventry. Mr. H. W. Chattaway, Trinity Churchyard, Coventry, architect:—

Haywood, C. ...	£2,859	0	0
Hill, C. G. ...	2,828	0	0
Herbert, H. S., Leicester ...	2,746	10	0
Garlick, C. (accepted) ...	2,704	0	0
Heatherley Bros. ...	2,628	0	0

Rest of Coventry.

**DARLINGTON.**—For the erection of a boys' school, to accommodate 390 pupils, for the Darlington School Board. Mr. T. W. Robson, Paradise-terrace, Darlington, architect. Quantities by Mr. H. T. Neilson, Darlington:—

Brick, stone, and plastering, including cement floors:—	£1,917	7	10
Marshall, G. ...	859	10	0

Carpenter and joiners' work:—

Jameson, W. ...	166	1	3
-----------------	-----	---	---

Slaters' work:—

Wharton, J. and G. ...	333	0	0
------------------------	-----	---	---

Plumbing and glazier:—

Smith, E. ...	37	19	0
---------------	----	----	---

Painter:—

Hoskins, W. H., and W. ...	37	19	0
----------------------------	----	----	---

All of Darlington.

Total, £3,313 18s. 1d.

Architect's estimate, £3,400.

**CHRISTCHURCH, HANTS.**—For the erection of iron fence at the Castle Hill, for the town council:—

Holloway, J. ...	£35	0	0
Howell, E. ...	83	10	0
Bayliss and Co. ...	24	18	0
Street, J. (accepted) ...	23	10	0

**EAST WICKHAM, KENT.**—For alterations and additions to the Forester p.h., Wickham-lane, for Messrs. Mitchell and Beasley, of the North Kent Brewery. Mr. J. O. Cook, of Eleanor-road, Woolwich, architect:—

Battley, Old Kent-road, ...	£581	0	0
Foreman, Plumstead, ...	515	0	0
Richardson, J. O., Peckham* ...	449	0	0

\* Accepted.

**EDINBURGH.**—For executing works of sewerage from the Inglis Green to Coltbridge, for the Water of Leith Purification and Sewerage Commissioners. Messrs. Cooper and Beaton, joint engineers:—

Best, J., Leith (accepted) ...	£20,128	1	6
--------------------------------	---------	---	---

**ELTHAM, KENT.**—For the completion of boundary walls and fences at Avery Hill House, for Colonel J. T. North. Messrs. J. O. Cook and T. W. Cutler joint architects:—

Smith and Sons, Norwood, ...	£815	0	0
Chappell, J. T., London (accepted) ...	739	0	0

**ESTON MINES.**—For the erection and completion of Salvation Army fort, for General Booth. Mr. J. W. Dunford, 101, Queen Victoria-street, E.C., architect and surveyor:—

Oliver and Gaudion ...	£695	10	0
Bulmer, T., South Bank ...	509	7	0
Radge, G., Normandy ...	499	5	0
Welsh, J., Stockton-on-Tees* ...	365	0	0
Lond, J., Middlesbrough* ...	354	10	0

\* Accepted.

**FOREST HILL.**—For erecting a Girls' Industrial Home and Laundry at Forest Hill. Mr. T. W. Aldwinckle, 2, East India-avenue, Leadenhall-street, E.C., architect. Quantities supplied:—

Waddington and Co. ...	£4,950	0	0
Roberts ...	4,625	0	0
Holliday and Greenwood ...	4,239	0	0
Todd, G. E. ...	4,149	0	0
Holloway Bros. ...	4,086	0	0
Lorden and Son ...	3,987	0	0
Johnson, W. ...	3,810	0	0

**GOREY, CHANNEL ISLANDS.**—For the erection of a Salvation Army fort, for General Booth. Mr. J. W. Dunford, 101, Queen Victoria-street, E.C., architect and surveyor:—

Le Rosignol, P., and Son, Rouge, Bouillon ...	£458	17	0
Springate and Baker, Gorey ...	394	0	0
Laurens and Le Corum and Son, St. Helier's ...	385	0	0
Viel, A., Jersey ...	369	0	0
Laurens, E. J., St. Helier's ...	362	10	0

**HERNE BAY, KENT.**—For the erection of new premises, William-street, for Mr. R. Moore, grocer. Mr. H. Farley, Richmond-street, Herne Bay, architect:—

Welby, C. ...	£1,520	0	0
Taylor, E. ...	1,363	0	0
Adams, G. ...	1,358	0	0
Farley, G. ...	1,350	0	0
Ingleton, A. J. (accepted) ...	1,347	0	0

All of Herne Bay.

**IDLE, YORKSHIRE.**—For the erection and completion of Salvation Army fortress in Idle, for General Booth. Mr. J. W. Dunford, 101, Queen Victoria-street, London, E.C., architect:—

Thornton, T., and A., Bromley ...	£792	0	0
Hobson and Son, Idle ...	788	0	0
Padgett, Idle ...	750	0	0
Obank, T., and Sons, Thackley* ...	721	0	0

\* Accepted.

**ISLINGTON.**—For certain alterations and additions to No. 225, Upper-street, Islington, N., for Mr. T. R. Roberts. Mr. J. Kingwell-Cole architect. Quantities by Mr. E. S. Mansergh, 28, Mount-street, Grosvenor-square, W.:—

Patman and Fotheringham ...	£2,150	0	0
Nightingale, B. E. ...	1,990	0	0
Drew and Cadman ...	1,882	0	0
Williams, G. S. S., and Son ...	1,816	0	0
Dove Bros. ...	1,645	0	0
Mowlem, J., and Co. ...	1,594	0	0
Neal, G. ...	1,546	0	0
Puzey and Lumley ...	1,525	0	0
Wall Bros. (accepted) ...	1,494	0	0

**KEMPSTON, GLOUCESTERSHIRE.**—For alterations and additions to the George Inn, Kempston. Mr. W. Drew, M.S.A. Swindon, architect:—

Glossop, T., Kempston (accepted).

**KETTERING.**—For shoe-factory, Kettering, for Messrs. Jessop and Jackson. Mr. H. Norwood, Broadway, Kettering, architect:—

Moulds, G. W. ...	£387	0	0
Wilson and Slow ...	359	10	0
Jessop, G. ...	333	0	0
Coltman, J. ...	321	0	0
Hart, J. W. ...	320	0	0
Jessop, W. H. (accepted) ...	320	0	0

All of Kettering.

**KETTERING.**—For two houses, Regent-street, Kettering, for Mr. S. Buswell. Mr. H. Norwood, Broadway, Kettering, architect:—

Wilson and Slow ...	£390	0	0
Moulds, G. W. ...	388	0	0
Hart, J. W. ...	375	0	0
Coltman, J. (accepted) ...	321	0	0

All of Kettering.

**KINGSBRIDGE.**—For the erection of two cottages, for Mr. W. R. Coles, Kingsbridge. Mr. W. M. Tollit, architect:—

Pearce, Kingsbridge (accepted).

Ten tenders received.

**LONDON.**—For pulling down and rebuilding Nos. 30, 31, and 32, Sandy's-row, Whitechapel, E., for Mr. J. Gabriel. Mr. J. O. Cook, of Eleanor-road, Woolwich, architect:—

Harris, North Woolwich, ...	£887	0	0
Battley, Old Kent-road, ...	870	0	0
Sharpe, Bow, ...	715	0	0
Richardson, J. O., Peckham* ...	714	0	0

\* Accepted.

## FOREIGN AND HOME PRODUCTIONS.

ONE general wail amongst manufacturers and builders is the increasing importation of foreign-made goods, the keen competition now existing in the trades connected with building, and the encouragement given to foreign labour. The markets of the world are thrown open to Englishmen without let or hindrance, and the foreigner competes with the English workman on his own ground. That this is discouraging to the manufacturer of high-class goods no one can doubt, and it is equally so to the building contractor who engages English labour. He finds in the continual importation of foreign-made furniture and joinery, the difficulty of persuading the public which is the best workmanship; the foreign-made articles are attractive and "shoppy" looking, it may be bizarre; full of what is called "cant"; but the average Englishman does not trouble himself about design or the technical points of joinery, if he can obtain the same article at a less price. How to convince the customer or employer of the superiority of home-made goods is one of the obstacles in the way of national industry, and should be the main endeavour of both capitalists and workmen. If conviction could be carried into the minds of employers that our English joinery is really better than the foreign imported joinery, the question of price would not be so serious a one, at least to those who can afford to pay for the better article; but it is this knowledge of technical points that is wanted. People now are not sure that a Swedish-made door is less durable and reliable than one made of yellow deal in this country; that a foreign-made piece of furniture is of so much less value than it looks to be. To show proof of the distinction is not so easily done, for it must be confessed a very large quantity of ordinary contractor's joinery done in the shop is not better, while sometimes it is worse, than high-quality American or Swedish work. The appeal is therefore fatal to the claims made for home-made work.

Before we can throw stones at other manufactures, we must prove the superiority of both the materials and labour of our own. The profession are aware that imported joiners' work of a selected quality is above the average joinery of the contracting builder, and they therefore prefer it for buildings of a certain class. Even the builder will sometimes admit that he cannot turn out doors or sashes so truly and well as those he can buy at a merchant or importer's shop. These admissions substantially confirm the opinion of the public that imported goods are equal at least to home-made productions. We cannot be surprised to hear of contractors buying their joinery or masons' work when they can do so at a less cost than they can manufacture the same at their own shops.

The reports of the delegates sent to examine the various branches of industry at the Paris Exhibition of last year are decisive as regards the building trades. To take French case-ments, the design of the joints in the stiles and bottom rails, the stuck mouldings, and the general finish are superior. The staircases display careful design and workmanship, well finished in detail. Belgium, Sweden, and the United States are keen competitors in machine joinery; there is less of the "slop-shop" than in many of the manufactures which come into our market.

One thing the expert notices is the bolder mouldings in foreign joiners' work; the hollows and rounds are large, and there is enough stuff in some of them to make two of our mouldings.

But the public are not the judges in matters of technical art. With all its apparent merits, machine labour has destroyed the characteristics which the architect or craftsman-designer values in the work. By the subdivision of the trades, the design of joiners' work has suffered to a large extent; a want of skill in detail and lack of finish are apparent. The machine is now made to compass all the work; the design must, therefore, be shorn of all those points which add to the labour, especially the hand labour. The mouldings are consequently designed with reference to the machine, the sizes those which can be conveniently worked with a profit. The productions are turned out roughly as they leave the machine, for although there is mechanical precision, there is no precision in finish. The fitting together is done by a separate set of hands, who have no sympathy with the manufactured pieces, and so the result is devoid of interest.

These results will continue so long as architects and operatives render themselves powerless—the first by accepting foreign machine-made labour, the other by shutting their eyes to the advantages that are open to them by trying to improve on machine labour. The workman, instead of endeavouring to check the tendency of machinery to sub-divide labour, is encouraging it by the apathetic indifference with which he regards all aids to supersede his own labour, and to dispense with food for thought. He does not see that it is only to the interest of large speculative contractors and manufacturers to encourage machine labour and sub-division of trade; that the effects of the system are to dwarf the mind of the craftsman. If we look at a piece of American-made furniture—a table, a chair, a pianoforte, or a cabinet, we discover a multiplicity of parts and details which force upon us the conviction that a number of hands have been engaged in its production: the ornament is lathe-produced or machine cut, the general effect fussy and inconsequential. Its very fussiness, however, is taken for ornament, and its beauty, if it has any, is the apparent accuracy with which the pieces have been put together. But it speedily loses its charm: the mind instantly discovers a wearisome repetition, and a want of fitness. It is all notches and chamfers; the ornament is largely composed of turned pieces, halves, and quarters. Of distinctive character and individuality it has none. The cabinet-making trade has suffered immensely since the introduction of machinery. The great impetus given to band and fret-sawing has not been without its effect in these productions. A tawdry class of ornamentation has sprung up; then the improvement made in machinery for veneer cutting has been injurious: veneers of mahogany, walnut, and maple are produced of the thickness of paper—witness the cheaper class of German and American pianofortes and tables. To compete with foreign workmanship of this class is the motive of many manufacturers. An inspector of factories, in reporting the condition of cabinet-making in London, has exposed the evil influences of this cheap labour. One large manufacturer told him that he could not pursue an exclusive trade of making up best goods. As an instance, he showed the inspector painted bedroom suites for shipment which he bought for less than £5 per suite, including a wardrobe, rather than make them, and out of his purchase he made a good profit. Further inquiries elicited the fact that no skilled workmen are engaged in the production of this cheap furniture: boys are employed, who pick up a certain branch of labour and stick to it. These boys are

called "slobbers," and will earn sometimes 20s. a week at the shops.

But the effects of foreign labour in design and workmanship have been equally felt in the building trades. Manufactures of ready-made joinery, mouldings, newels and balusters sell largely—American and Swedish goods, which are made on the principle of getting as much out of the material as possible at the cheapest cost for labour. Two essential qualities are inherent in their production: meagreness and want of character. The first is noticed in the scanty mouldings, the want of substance, the little manual labour bestowed on the joints and putting together: the latter is shown in the monotonous sameness, the lack of individuality. The individual expression of the executant is completely lost in the mechanical. We cannot help seeing this lack in the turned balusters, the framing, and doors which are turned out by the hundred from the same machines. Well may one writer call it the "grinding devilry of steam machinery," which has deprived the brain and hand of their skill and labour. The architect and the artisan are, we say, to blame for not making a stand against the increasing employment of machinery for labour which ought to be done by hand. If the architect insisted on designing the joinery and fittings of his buildings, the large importation of foreign machine-made goods would cease; there would be more opportunity for skilled labour in this country, and architecture and art would be again restored to their old prestige. How much also could the craftsman do to turn his brain to account by turning from the mere minding of machines to execute and design!

Machine-made joinery, both foreign and home produced, will necessarily hold its own when large quantities of one size and pattern are required. In workhouses, factories, barracks, and such like buildings, the machine-made doors and windows are acceptable, and the imported goods are cheaper; but we maintain that for a higher class of buildings, the difference between foreign and home manufacture is too slight to be considered. Builders having a good stock of material and skilled hands are found anxious to execute the work on their own premises, so as to employ their men. The actual results are patent to everyone who understands workmanship. The best joinery is undoubtedly that turned out by our good firms, and prepared from the architect's details. We at once know it by the character and style of the staircase balustrading, the panelled dados, the moulded doors and architraves; the expression of the executant craftsman, the personal element of the designer, are manifested in every piece of joinery or fitting in the building. On the other hand, one may see hundreds of houses in the West-end suburbs—having doors, handrails, balusters, and mouldings of exactly the same pattern. One sees at a glance they have been turned out wholesale; that the houses have been built for them, or else made to take them, whether suitable or not for the particular purpose. The speculative builder has the knack of using the imported goods to the best advantage; so he contracts with some bricklayer to erect a row of houses of the same design with certain openings; the importer of foreign joinery supplies the whole of the interior—doors, windows, and fittings—which are the most expensive items in house-building.

The recourse to task work is another of the grievances amongst workmen, especially plasterers. The "labour only" system has encouraged the taskmasters in the building trades without improving the quality of the labour. We cannot wonder, when competition is so rife, that task-work is preferred to day-work. While America, France, Germany, and Holland are competing with the English workman in the marts of the world,

the cheapening of labour must follow as a matter of course. Mutual concessions by masters and workmen, and an earnest endeavour to control machine production, are the only means of preventing hand-labour being entirely subverted, and the craftsman turned into a machinist. No worse consequences could befall art-craftsmanship, for if we value style we must promote the individual and complete executant. Machine labour can be controlled within certain limits; there is a large and rapidly-increasing domain for its exercise without encroaching on the hand-labour of the artisan.

#### ARCHITECTURAL BRICKWORK.—XXX.

##### MOULDED ARCHES.

A MOULDED arch of any depth may be described as a recessed arch with the outer edges of the bricks moulded; and, therefore, in designing an arch of this description the most desirable plan is first to decide upon the number of separate and concentric arch-rings, one within the other, and then to design the mouldings. The thickness of the wall should, of course, be the primary consideration, as upon it will depend the number of recessed rings. Thus in a wall of a brick and a half thick, it is possible to obtain three  $4\frac{1}{2}$ in. rings, the edge of each of which can be moulded, or if only

two rings be used, one of them may have a bolder moulding. In sketch 1 we give a view of the elliptical arch of the main gateway to the courtyard of Layer-Marney Towers, Essex. The arch has three distinct rings, each of them moulded. The plan of jamb, and the elevation of the apex of arch, Fig. 2, a, b, c, d, will show how the separate rings are worked. It will be noticed that two bold hollows give a shadowed background to the mouldings which project, and admirably separate and add value to them. On the outside is a splayed brick, next comes a portion of the hollow, a roll-member and fillet which form the centre projecting member; third, a hollow, and another roll member in the inner or soffit portion of arch. The hollows might have been square re-entering angles, as in ordinary arches of three recessed members, in which case the joint would have been at the angle. As it is, the hollows disguise the joints between the rings. The design of moulding is certainly more suitable to stone than brick; or to terracotta, in which the arch bricks can be moulded to a large size.

##### VAULTED ARCHWAYS.

In vaulted archways, the gauged and rubbed outer arch need not be continued throughout the vault, but be employed to hide the extremities of it. Very often the outer ornamental arch is made a sort of drop arch, lower but concentric with the vault behind it, forming a rebate on the

inside for the gates to close against. The advantage of this arrangement is, that there is no unsightly joint visible between the two arches on the soffit, for the bond is broken on the angle of rebate, and the outer rubbed arch makes a clean stop against the rougher arch of vault. For strength the plain, flat-faced arch is, perhaps, to be preferred to the moulded arch, for, instead of separate rings, the joints are made to radiate to the centre throughout the thickness, and the bond is preserved by breaking the radiating joints by cross-joints, as in English bond.

##### ARCH BOND.

Col. Seddon remarks: "Flemish bond is seldom used, except, perhaps, in arch rings 9in. deep, not being so strong; moreover, the bats which would be required in arch rings, being an uneven number of half-bricks in depth, would be most undesirable." For strengthening deep arches composed of half-brick rings, or to tie the rings together, it is often desirable to use bonding or "lacing" courses at intervals. These lacing courses are inserted at those parts of the arch where the radiating joints of the separate rings coincide, and they act to distribute the pressure on the whole of the rings. For small arches or vaults they are not necessary, however.

##### ORNAMENTAL WINDOW ARCHES.

Sketches 3 and 4 represent forms of elliptical window arches, often met with in brick buildings. The first is from a brick villa near Streatham, and is composed of two rings of moulded bricks, set one within the other, and a label moulding over. We give it as an effective form of arch for a 9in. reveal composed of two ordinary "quarter-round" moulded bricks. With the moulded label the arch has a rich appearance. Fig. 4 represents a brick window arch taken from an old gable at Ypres in Belgium, a city replete with ornamental gables and traceried arches. These have generally labels of stone or brick, as in the sketch, and the window-heads, or tympana, under the outer arch are generally recessed and relieved by brick or stone tracery. We will give other examples of the moulded brick window-head in which there is generally a roll member between hollows or squares.

##### TENEMENT HOUSES.

THE subdivision of buildings into separate dwellings, no less than the throwing open several distinct houses into one business establishment, ought to be placed under the jurisdiction of properly constituted authorities. We are not now referring to the self-contained residential flat. In the Metropolis it is optional with any person to divide his house internally, for although there are certain provisions in the Metropolitan Building Act which deal with buildings tenanted by different persons or are let to separate families, they are practically powerless to interfere with the alterations that are made in dwelling-houses of a small area. The only rules which apply are the following: "That separate sets of chambers tenanted by different persons, if contained in a building exceeding 3,600sq.ft. in area, be deemed to be separate buildings, and be divided vertically by party-walls or horizontally by arches or fireproof floors" (sec. 27); also sec. 22, which says that in every building "containing more than 125,000c.ft. and used as a dwelling house for separate families, the floors of lobbies, corridors, passages, landings, and stairs shall be of stone or other fireproof material." Now, practically, the 3,600sq.ft. of area in sec. 27 excludes by far the larger number of buildings used as dwellings or offices, and only applies to large blocks of offices measuring over 100ft. by 35ft. Again, the 125,000c.ft. excludes all ordinary dwelling-houses of the usual size which are let for separate families. There is, there

fore, nothing to prevent a lessee converting his five or six-storied house into separate tenements for families or dividing it into separate chambers for different persons. A very large proportion of London five-storied houses in Bloomsbury and Kensington are sub-divided and let to different persons and families, which were designed and built for one family only, and these houses, to be estimated by the hundred, are exempt from any interference or restriction. A floor of three bedrooms is let off to one or two families, and every floor is thus occupied, making in very many cases eight or ten families in the house. From a sanitary point of view, the mere crowding together is objectionable enough; but there are more dangers to be apprehended from the structural and sanitary unfitness of the houses so occupied. The risks of fire are increased to a large extent, for there are no fireproof walls and floors between the separate sets of rooms; the floors of the lobbies, landings, and passages are usually of wood; the single staircase, which is the only means of ascent and descent, is of combustible material, so that the sections of the Act we have quoted are set aside in the large majority of buildings. It is clear the framers of these sections had in view only the building of large blocks of chambers and sets of flats, and did not contemplate the conversion of quite half the residential buildings of London into lodging-houses. If we walk through any of the central Metropolitan districts, we shall find in all the older neighbourhoods the houses sub-let; the heavy rents are prohibitive of single-family occupation. What are the consequences of the custom? Their structural adaptation is a secondary consideration with those who take houses for the purpose of eking out a livelihood; no matter if the walls are wooden partitions only, the staircase and passages unequal to the task. Sanitary defects are more apparent: there is only one set of conveniences for the whole of the inmates, and these are located in the centre of the house, perhaps on the first or second-floor landing. Each family on the ground or top story has to come up or go down to the middle floor if he wants to take a bath or wash his hands; the closets are equally inconvenient; the taps, the larder, the kitchen offices are not within reach; each family has to cook on its own floor, or depend on the housekeeper. The appliances of a well-ordered lodging house or set of flats are not found in these houses. Clause 2 of Sect. XXVII., which we first quoted, speaks of division by party-walls and fireproof floors as a separation of rooms tenanted by different persons; but the clause is not very clear. The question occurs, How is a party-wall to be treated when it runs along the side of a corridor or a staircase? In Clause 3 it states: "If any building in one occupation is divided into two or more tenements, each having a separate entrance and staircase, or a separate entrance from without, every such tenement shall be deemed to be a separate building." The comment we have to make on this provision is that the Act regards as a separate building a properly-divided set of rooms, having its own entrance and staircase, but does not so regard the separate tenements in houses which have been converted without their sanction or control. The provision, in fact, encourages the evasion of the Act. A house may be crammed with different families or separate lodgers with only one entrance and stairs, without the control of the surveyor; but if a separate entrance be made, each tenement comes under the operation of the Act. Where is the justice of this distinction?

It is unnecessary to say more on the unsatisfactory state of the building regulations of most towns as regards the sub-division of buildings. That there should be some restrictions appears evident from the disclosures now and again made in the public press. Until the building legislation of the

Metropolis steps beyond the older motive of the statute—namely, to prevent the spread of fire—and considers the dwellers and the dwellings in their social and sanitary aspects, we cannot hope for much improvement. The Institute, who are engaged in discussing the amendments in building legislation for the county of London, should exercise some influence in these matters. The considerable conversion of buildings from their original purpose now going on ought to be under the control of the County Council, and regulations be framed to meet every case of alteration.

#### CONTEMPORARY BRITISH ARCHITECTS.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

THE six portraits printed herewith to-day will make no less than fifty photographs already given in our pages since the beginning of the year, of architects whose names are more or less familiar to our readers. In accordance with our previous plan, we give some few particulars in each case.

Mr. Henry Louis Florence, F.R.I.B.A., was a pupil of Mr. E. C. Robins, F.S.A. He also passed some years in the offices of the late J. R. Hakewill, F.R.I.B.A., and F. P. Cockerell, many years hon. sec. of the R.I.B.A. He subsequently proceeded to Paris and entered the atelier of the late M. Questel. On his return to England he gained in rapid succession the Tite Prize and the Soane Medallion and Scholarship at the R.I.B.A. He further obtained the Gold Medal for 1869 and the Travelling Studentship for 1870, awarded by the Royal Academy of Arts. After a year's travel in Italy he commenced to practise on his own account in London. His first work of importance was a bank, with the premises adjoining, in Broad-street, Worcester. He was also one of the six selected for the final competition for the Shakespeare Memorial Theatre, Stratford-on-Avon. For many years he had taken an active part in the work of the Architectural Association, and in 1878 he was elected its President. In the previous year he had entered into a partnership with Mr. L. H. Isaacs, M.P., F.R.I.B.A., which terminated in 1887. During that period, in addition to many works of minor importance, the following buildings have been executed from their designs:—The Holborn Town Hall; the new Library for the Honourable Society of Gray's Inn; the Paddington branch of the London Joint Stock Bank; a mansion in St. James's Park and Delahay-street, for Mr. Ed. Lloyd; extensive additions to Wood's Hotel, Farnival's Inn; business premises for Messrs. Farniloe in Rochester-row, for Messrs. Maxwell in Bell-yard, and Messrs. Lamplough in Holborn; the Hotel Victoria, Northumberland-avenue. They also obtained the first premium for the proposed new Town Hall, Bethnal Green. As joint architects they have recently completed a new block of buildings in Northumberland-street, for the Constitutional Club, and are about to commence an extensive block of buildings in Tooley-street, for the South-Eastern Railway Co. The photograph from which our illustration is taken is by Mr. Vandyke of Gloucester-road.

Mr. Campbell Douglas, F.R.I.B.A., of Glasgow, a Member of the Council of the Royal Institute of British Architects, was born in the village of Kilbarchan in Renfrewshire, in 1828, where his father was the parish minister. He served his apprenticeship with the late John T. Rothead, of Glasgow, who was a capital architect and clever man. Afterwards Mr. Douglas spent five or six years in various offices in Belfast, Liverpool, Brighton, and finally with the late Mr. John Dobson, of Newcastle-on-Tyne, one of the best known architects in the North of England. Mr. Douglas began business for himself in 1855. After some years an old college friend, Mr. John J. Stevenson, F.S.A., now of London, was with him in business for some years, and latterly Mr. James Sellars, the architect of the International Exhibition of 1888 in Glasgow, when Mr. Douglas was unwell in South Africa. He returned home in vigorous health in April of that same year. Mr. Sellars died in the following October. The following annexed selection of the more important buildings designed by Mr. Campbell Douglas may be divided into three lists, A, B, and C. The first

of these were personal works, the second series names of buildings erected in conjunction with Mr. Stevenson, and the third those done in partnership with the late Mr. Sellars. A.—Churches: Alloway Church, Ayr; Blackfriars Church, Glasgow; Free S. Enoch's, Glasgow; North Leith Free Church, Edinburgh; St. Andrew's Free Church, Edinburgh; Dysart Free Church, Fife; Cupar Free Church, Fife; Hampstead Presbyterian Church, London; Bournemouth Scotch Church. Country houses: Auchenhiglish, Loch Lomond; Sir William Thomson's, Netherhall, Largs, Ayrshire; Greystane for Mr. D. M. Watson, near Dundee; Hartfield House, Cove, Dumbartonshire; Ralston House, near Paisley; Kiel House, Campbeltown. Public buildings: St. Andrew's Hall, Glasgow; Cupar-Fife Corn Exchange; Scottish Amicable Insurance Offices, Glasgow. B.—Kelvin-side Free Church, Glasgow; Clarendon Wesleyan Church, Glasgow; Townhead Established Church, Glasgow; Westerlea House, Edinburgh, for Mr. Charles Cowan. C.—Finnieston Free Church, Glasgow; Free Anderson Church, Glasgow; Belhaven U.P. Church, Glasgow; Ayr Town Hall; Dysart Buildings, Fife; Victoria Infirmary, Glasgow (now in course of building); Wyke and Lockhead's Warehouse, Glasgow; Glasgow Herald Buildings; New Club, Glasgow; Kelvin-side Academy, Glasgow; Spier's School, Beith, Ayrshire; and Anderson's College Medical School. It may be interesting to note that the designer of the BUILDING NEWS headpiece was an old pupil of Mr. Campbell Douglas—viz., the late Mr. Bruce Talbert. The portrait given herewith is by Messrs. T. and R. Annan, of Glasgow.

Mr. John Holden, F.R.I.B.A., represents Manchester on the Council of the Royal Institute of British Architects. He was elected Fellow in 1877, and a Fellow of the Surveyors' Institute in 1874. He is a Past-President of the Manchester Society of Architects. His practice, which has included several churches and Nonconformist chapels, besides numerous mills, factories, and warehouses, may be described as one of general character. His position as Arbitrator in questions of building disputes and of light and air is well known. His photograph was taken by Messrs. Mudd and Son, of Manchester.

Mr. John Dando Sedding, F.R.I.B.A., of London, was for some time in the office of the late Mr. Geo. Edmund Street, R.A., and commenced practice at Bristol. His connection with the Art Workers' Guild and the Arts and Crafts Exhibition is familiar to our readers, and many of his designs both for buildings and decorations have been illustrated in our pages. He is the Diocesan Architect for Bath and Wells, which post he obtained on the death of the late Benjamin Ferrey, F.S.A. In Cornwall and the West of England Mr. Sedding has restored many churches, and the following is a list of the chief works which he has done:—Netley Castle, Hants; Holy Trinity Church, Chelsea; St. Clement's Church, Bournemouth; country houses for Col. Wynch, Knole, Dunster; Mr. Charles Rowcliffe, Halsway, Somerset; the Rev. H. Griffith, Glasbury, Herefordshire; and Mr. Edmund Christie, Bournemouth. He built the Children's Hospital, Finsbury, adjoining the Convent of St. Mary at the Cross. He has built new churches at Falmouth, Hayle, Netley, St. Augustine's, Highgate; the Church of the Holy Redeemer, Clerkenwell; and another at Wincanton. The restoration of the great screen, Winchester Cathedral, was commenced by Mr. Sedding; and he has erected numerous parsonages and small houses in various places. A new church at Ealing is proposed to be built from his plans. He has been associated with the annual excursions of the London Architectural Association, and has lectured on art subjects before that body. The photograph given to-day is by Mr. Mendelssohn, of Kensington.

Mr. John L. Robinson, A.R.H.A., member of the Council of the Royal Institute of Architects of Ireland, has for many years acted as hon. photographer to the London Architectural Association annual excursions. He is chairman of the Kingstown Commissioners and a member of the town council of the city of Dublin. The Dublin Sketching Club owes much to his energy and interest in its work and meetings. The excursion to Ireland a year or two ago by architects from London was to some considerable extent organised by Mr. Robinson.

He now is actively engaged on behalf of the city authorities with a scheme for the lighting of Dublin by electric light, and he has given evidence before Select Committees of the House of Commons on the question of house property and rating in County Dublin. The following is a list of a few of his works: Kingstown Town Hall; St. Michael's Hospital, Kingstown; St. Saviour's Dominican Priory, Dublin; completion of Mater Misericordiae Hospital, Dublin; St. Patrick's Training College, Drumcondra; the Female Training College, Baginbun-street, Dublin; Convents of Mercy at Kingstown, Brickfield-lane, Dublin, and Newport; Industrial Schools at Booterstown and Goldenbridge; schools at Dundrum, Rathnew, Dolphin's Barn; Houses at Glengageary, Dublin, &c. His photograph was taken by Messrs. Chancellor, of Dublin.

Mr. George Ashdown Audsley, F.R.I.B.A., of London, whose portrait concludes the selection comprised on our sheet to-day, was a pupil of Messrs. A. and W. Reid, of Elgin, where he was born in 1838. He was for many years in practice with his brother in Liverpool, during which time the following buildings were erected from their designs:—Church of St. Margaret, Belmont-road, Liverpool; Christ Church, Kensington, Liverpool; Church of St. Mary, and the Mausoleum of the Preston family, Ellet Grange, Lancashire; the Welsh Church, Princes-road, Liverpool; the Welsh Church, Chester; the Welsh Church, Garston, Lancashire; and the Welsh Church at Wrexham. They also built the Jewish Synagogue, Princes-road, Liverpool, a building which was richly decorated throughout by the architect. Some years later the Jewish Synagogue, St. Petersburg-place, Bayswater, W., was designed by Mr. Audsley, in conjunction with Mr. S. N. Joseph, of London, who superintended the carrying out of the work. The Racquet Club-house and Courts in Parliament-street, Liverpool, one of the most complete establishments of the kind in England, was Mr. Audsley's work. He restored the following churches:—Babington Parish Church, Cheshire; Huyton Parish Church, Lancashire; Prescott Parish Church, in the same county. He designed Streatham Tower, Prince's-road, Liverpool; The Towers, Sefton Park, Liverpool; and numerous other important houses in the neighbourhood of Liverpool. The Picture Gallery of the Liverpool Art Club is his latest most noticeable work, and another is the Layton Art Gallery, Milwaukee, U.S.A., a building of importance designed in the Neo-Grec style, severely treated. We illustrated the design a few years ago. Mr. Audsley's publications are numerous, and some of them are of world-wide reputation for their artistic value and beauty of execution. His illuminated works include "The Sermon on the Mount," large folio; "The Prisoner of Chillon," 8vo.; "Guide to the Art of Illuminating and Missal Painting." His architectural works are: "Cottage Lodge and Villa Architecture," folio; "Popular Dictionary of Architecture and the Allied Arts," not yet finished. These were followed by a remarkable series of art books, viz.: "Polychromatic Decoration as applied to Buildings in the Mediaeval Styles," folio; "Outlines of Ornament," folio; "Handbook of Christian Symbolism"; "Christmas and Easter Decoration of Churches"; "Taste v. the Fashionable Colours"; "The Ceramic Art of Japan," 2 vols., folio. In this work Mr. G. A. Audsley was assisted by Mr. James L. Bowes, the well-known collector. "The Ornamental Arts of Japan," 2 vols., folio. This work, probably one of the finest art books ever published in England, was subscribed by the American publishers at three and four times the English price, the artist's proofs being sold at £82 per copy. (The English price was £21.) His works now in hand are: "The Practical Ornamentist," a work of everyday use for the practical decorator, 100 plates in gold and colours, folio; "Handbook of the Organ," a comprehensive treatise on the art of organ building. In addition to the above, Mr. Audsley has written several Descriptive Catalogues of art collections and exhibitions. He has delivered several public lectures on musical and art subjects, and read many papers before learned societies in England and America. He is now engaged in writing a series of articles for "The Building News" on "The Symbolism and Iconography of Early and Mediaeval Art," and a series of articles for "The English Mechanic," entitled "Acoustics: A Review of the Old and

New Theories of Sound." Mr. Audsley has given much attention to all matters connected with the art of organ building, and recently contributed to "The English Mechanic" a complete series of articles on "The Church Organ, the Concert-room Organ, and the Chamber Organ," and last year delivered a lecture before the London Musical Association on "Matters, chiefly Architectural, relating to the Accommodation of the Organ in Churches and other Buildings." His portrait, reproduced to-day, was taken in New York, by the "Bonnadtype Company."

## MASONRY AND STONE-CUTTING.\*

By LAWRENCE HARVEY.

[TWENTY-EIGHTH LESSON.]

CORBEL ARCH ON THE PROJECTING ANGLE OF A BUILDING.

TWO walls (Fig. 183) meet at an angle, A C B, which in our figure we have taken to be a right angle. Now, as an easement to the footway, the angle A C B is to be removed on the ground floor of the building, but yet left in the floors above. This can be done by a conical corbel-arch, the apex of the conical soffit being placed at the meeting of the vertical planes A S and B S taken parallel to the outside walls, and at an equal distance from the angle C. The surface on plan A C B S covered by the corbel-arch will then be a square, and the directing curve or base of the cone a semicircle of diameter A B, thus giving a cone of revolution for the soffit of the arch.

The base is divided in an odd number of symmetrical parts, diminishing from the springing to the crown, in order to obtain a more equal division in the joints of the face-arches. The bed-joints will then be planes passing through these division-points and the centre line S O of the cone. The joint-lines on the soffit will be the generators (S' d') (S' e', S' f'), which, prolonged to the vertical plane A C of the wall, will give us the points D E . . . D' E' . . . of the face-arch. The face-arch, being the section of a cone by a plane parallel to one of its generators, is, of course, an arc of a parabola. To obtain the point C' of the face-arch, turn down the generator to S A on the plan, turn down also the angle of the wall at right angles with the centre line S C, then C' where it cuts the generator has only to be lifted up to its position in C' on the elevation by describing a circle round S'. The same construction might be used for finding the other points of the face-arch; E would come to E<sub>2</sub>, and D to D<sub>2</sub> on the turned-down generators.

To draw the mould (Fig. 185) of the face-arch, we turn the plane of the wall round a vertical axis in Z (Fig. 183); every point (E, E') will remain at the same level in E"; the joint line E' F' will naturally, when prolonged, pass through the point γ below the angle of the wall on the level of the springing.

Please note that the lines are drawn full on the plan (Fig. 183) as if seen from below, and that the elevation (Fig. 184) is merely explanatory, but useless in practice, the master mason requiring only the mould (Fig. 185), which he can draw direct from the plan (Fig. 184) by cutting each vertical e E' (Fig. 185) by an arc of a circle of radius γ E' equal to C E<sub>2</sub> (Fig. 183).

The eye will begin with the vertical circle (a b, a' b' m' b'), and the joint, being formed of a series of normals to the conical soffit, will be a zone of a cone with apex in w. This joint will be limited in a β by another circle, and the rest of the eye will be a cylinder as shown in Fig. 186.

To cut the eye, produce a cylinder (Fig. 186) of base a<sub>2</sub> z<sub>2</sub> β<sub>2</sub>; on the plane of the base draw circle a l m b; on the cylinder draw line a λ μ β; divide both the circles in an equal number of parts and join corresponding points by chisel-drafts: this will give the conical joint. To cut out the soffit, draw triangle a S b on the lower plane of the eye, and join all the points of front circle with the point S.

**Bed-joint Mould of Arch Stone.**—Turn down the plane of the joint E' S O round the centre line S O of the cone; the point (E E') will come to E<sub>2</sub>, and the arris on the face wall will take the direction C E<sub>2</sub> F<sub>2</sub>; the length E<sub>2</sub> F<sub>2</sub> is equal to E' F' (Fig. 185). The normal m μ, when turned down, comes upon a a, and the mould is then f<sub>2</sub> F<sub>2</sub> F<sub>2</sub> a a P. The other bed moulds are drawn in the same way.

**Soffit Operation Planes** (Fig. 187).—These are the faces of the pyramid inscribed to the cone and having the joint lines as its arrises. To draw it produce an arc of a circle with radius S<sub>2</sub> A<sub>2</sub> equal S A (Fig. 183); carry thereon chords A<sub>2</sub> i', i' d', d' e' . . . equal to chords on the base of the cone (Fig. 184); draw corresponding radii and prolong them until S<sub>2</sub> I<sub>2</sub>, S<sub>2</sub> D<sub>2</sub>, S<sub>2</sub> E<sub>2</sub>, . . . be equal to the corresponding lines on the bed moulds. Join the extremities by straight lines A<sub>2</sub> I<sub>2</sub>, I<sub>2</sub> D<sub>2</sub>, D<sub>2</sub> E<sub>2</sub>, . . . Then cut off from the arris-lines the length S<sub>2</sub> a<sub>2</sub> equal to S a. For the key-stone there will be a triangle beyond E<sub>2</sub> E<sub>2</sub>, the sides of which are of length E<sub>2</sub> γ<sub>2</sub>. To find this length, draw (Fig. 183) S R, the trace of the operation-plane for the soffit of the key-stone; turning R to R' on Fig. 185, E' R' is the trace of the operation-plane on the face-mould, and E' γ' is the length required.

To complete the operation plane, the curve l<sub>2</sub> φ<sub>2</sub> m<sub>2</sub> intersection of that plane with the conical eye-joint is required. Take point d' on chord d e' (Fig. 184), and through this point take a plane S' d' O cutting the operation plane and the eye-joint. The section of operation-plane turned down round centre line gives S δ; the section of the eye-joint turns down on a a, and thus φ is on the intersection of these two lines. Carry length S φ on S<sub>2</sub> φ<sub>2</sub> (Fig. 187), and draw the curve.

To work the stone from the soffit operation-plane a bevel must be used equal to the solid angle comprised between the operation-plane and the wall face. The shortest way of finding this angle is as follows: The intersection of the two planes is projected on R A C (Fig. 183), and shown in E' D' V' (Fig. 185). If a plane be taken through line A S, and perpendicular to the above intersection, this plane will cut the wall-face along the line A' T' (Fig. 185), which is turned down on the plan in A T (Fig. 183) when the plane revolves round A S. But T S is then the position of the section made by that plane in the soffit operation plane, and the angle of the bevel required is R T S (Fig. 183).

The working of the arch-stone is done as in the former corbel-arch studied (Fig. 188).

The construction given is that used during the Renaissance, with some variations as to form of soffit. Sometimes the soffit is spherical; sometimes it is a cylinder, with springing line coinciding with the bevel of the angle. In all these cases the principle of the construction is essentially the same: it consists in an arch, the bed-joints of which radiate from the line which bisects the angle on plan. Now, it is evident, that the thrust of such an arch must tend to throw over the walls at the angle. If it do not so in practice, it is because these arches are only used on a small scale. There is another result also to be feared when such corbel arches are used on a large scale. The weight of the wall overhanging the corner will act as a lever, with the line A B as its fulcrum, and tend to fall out into the street, and is only prevented from doing so by being tied by mortar, cement, or iron clamps to the remainder of the wall on both sides. On the other hand, by the use of twisted bed-joints, I believe corbel arches of any size might be constructed to support the angle of a building, provided that the keystone be firmly tied to the body of the wall by iron, or, better, by bronze, chains. But as I have never seen any such construction, nor produced one myself, I shall for the present abstain from giving a more detailed description of my idea.

These corbel arches have been often used for carrying the landings at the angles of rectangular staircases in connection with raking vaults which carry the steps as in Fig. 189. Such staircases are most noble in appearance, and have the practical advantage that the steps may be replaced when worn out without interfering with the structure of the walls. In constructing such vaults, begin by the corbel arch; then take the parabola of its section by planes A C and B C, and use these parabolas as the guiding lines to the cylindrical vaults supporting the steps. To prevent the uppermost course of stones from slipping down it should be jointed as a flat arch, or a rebate a in L may be made. The corners of such stairs are sometimes treated as groins (Fig. 190); but they do not look so well as when finished with a corbel arch.

A plan and report by Mr. J. F. Trew, of Gloucester, for the sewerage of Dursley, has been adopted by the rural sanitary authority. The estimated outlay on the scheme is £3,750.

## ARCHITECTURAL ASSOCIATION.

THE fortnightly meeting of the Association was held on Friday evening, the President, Mr. Leonard Stokes, occupying the chair. The following new members were elected:—W. G. Legg, S. H. Gordon, G. H. Gill, H. B. Cresswell, H. S. Morris, J. Robinson, and H. T. Bromley.

## ARCHITECTURE IN OXFORDSHIRE.

A paper on this subject, written by Mr. W. A. PIRIE, and illustrated by numerous plans and sketches, was read by Mr. HOOPER for the author, who was absent owing to indisposition. Mr. Pite found in Oxfordshire an abundant field for study and sketching, and during a four months' tour he was only able to deal with four of the principal parts of the county—Bloxham, King's Sutton, Witney, and Burford. The author urged the importance of systematic and patient analogy as the only means to acquire a thorough knowledge of a building and to understand the architectural dialect and idiom of the district examined. When an architect had village districts to study, it was important and necessary to have some system to work on, but not rigidly for conformity. Without question, the best course was to see everything first inside and out the building to be examined. Mr. Pite added: Without exception, make a plan to a small scale; this you may easily do by pacing and sketching in the detail. This may seem rough, but you will find it afterwards to be of the utmost importance. The late Mr. James Parker, the well-known antiquary of Oxford, showed me a wonderful collection of plans which, with his sketches, were kept in a strong room; he adopted a useful method of tinting the walls to indicate the several dates. This should be supplemented by a brief description of the church, with illustrated notes. Then if the nave arcade calls for illustration, measure one bay, plotting to  $\frac{1}{4}$  in. scale, on the spot, mouldings  $\frac{1}{2}$  or  $\frac{1}{4}$  real size, with the jointing and sculpture carefully noted. Much of the history of a church centres around the nave arcades, and both are constantly found to be dissimilar in dimension, date, and design. Chancel arches, sedilia, and pulpits have their several claims; while screens, rood-lofts, and benching may be best secured, full size, by rubbing the fillets on stout straw paper with heel-ball, and filling in the details, sculpture, and mouldings full size. Then there are porches, generally of remarkable beauty; the sweetest part of all to work in. Then the enchantments and mysteries of ancient roofs, perhaps their slightly inaccessible position gives us an increased desire to penetrate the secrets of their scantlings. But, whatever you do, give a loyal preference to the rational and practical measured detail, than to an irresponsible and too often questionable freehand sketch. Give the best of your time and strength to good figured work, and at its close the zest of anticipation and change of occupation will enable you to produce spirited, and, in more probability, accurate, sketches of any portion of the edifice you may wish to secure. Mr. Pite proceeded to describe in detail the principal churches sketched during his tour. In the northern part of the county were three important churches—one, certainly, in Northants, but separated only by a canal; but the three within sight, a few miles south of Banbury, each being celebrated for a spire of singular beauty. A local rhyme discriminated between their merits in the following doggerel: "Bloxham for length, Adderbury for strength, King's Sutton for beauty." These churches were a study in themselves, in their influence on one another. They were visited by the A.A. excursion in 1884. At Bloxham the most interesting features were the admirably arranged tower and spire; the delicate Norman carving in the chancel, quite equal to the Romanesque work to be seen at Bamberg and elsewhere in Germany; the painted chancel screen and two-storied porch. At Adderbury the rich detail of the chancel—a fine specimen of William of Wykeham's work—demanded careful study, with the brasses, rood-loft and screens, and magnificent cusped 14th-century roof of open timber. In the neighbouring church of King's Sutton, the same hands seemed to have been at work; the wondrous symmetry and simplicity of the famous spire were enchanting. The great church of St. Mary, at Witney, was described in detail; it contained much work of the 11th, 13th, 14th, and 15th centuries. The last church described was that of Burford, restored by the late G. E. Street, which for concentrated interest excelled all

others in the county, while it was also grandest in scale.

At the close votes of thanks were accorded to the author and reader of the paper, on the motion of Mr. H. D. Appleton, seconded by Mr. L. A. Shuffrey, and supported by Messrs. F. R. Farrow and C. H. Brodie.

## BUILDERS' CLERKS' BENEVOLENT INSTITUTION.

THE twenty-third annual general meeting of the donors and subscribers took place on Tuesday, at 21, New Bridge-street, E.C. Mr. H. H. Bartlett (president elect), occupied the chair, supported by Mr. E. Brooks (treasurer), Messrs. E. C. Roe, H. W. Parker, C. K. Turpin, J. Robson, T. H. Winny, E. B. Gammon, A. A. Stanger, W. D. Gilbert, and others. Mr. Wheatley, the secretary, read the report, which stated that during the past year the income had been well maintained, the amount received being £288 12s. annual subscriptions, £317 19s. donations, and £98 7s. 5d. dividends, total, £704 18s. 5d. The expenditure was £472 11s. 7d., of which amount £377 18s. 4d. was for pensions and temporary relief. Two elections had been held, the result being that Mrs. Charlotte Tucker and Mrs. Susan H. Fisher had been added to the pension list. One pensioner, Mr. J. T. B. Miles, had died during the year, leaving a present total of nineteen pensioners now on the books, and three children at the Orphan Working School, per presentation of the institution. The eleventh annual dinner took place at the Holborn Restaurant on the 2nd April, 1889, Mr. John Aird, M.P., presiding, when subscriptions and donations were announced amounting to £350. A further purchase of stock had been made during the year, bringing up the total of invested funds to £3,650. The committee announced with great regret the death of Mr. Chas. Richardson, one of the trustees, and also a vice-president of the institution. Mr. Richardson had been a regular and liberal supporter of the funds from the foundation to the period of his lamented decease. The report concluded by thanking the master builders, architects, and merchants connected with the building trade for their past help, and expressing the hope that the usefulness of the institution might be well maintained. The chairman, in moving the adoption of the report, expressed the pleasure it gave him to find the institution in such a flourishing condition. Much had been done during the past year in assisting widows and those who needed relief. Additional funds had been invested, and the balance at the bank was satisfactory. He moved: "That the report and balance-sheets, as read, be adopted and printed, together with a list of subscribers and rules of the Institution." Mr. E. B. Gammon seconded the resolution, which was carried. Mr. E. C. Roe, in proposing a vote of thanks to the ex-president and other retiring officers, remarked that Mr. Aird's Parliamentary and other duties had prevented his attendance at the ordinary committee meetings; but he had done the institution good service in having acted as president. As to the future, there was one thing to consider, having reference to the increasing number of pensioners; and that was the importance of increasing the invested funds, so that a steady income might arise from this source, and that those whom they took an interest in as pensioners might not have to depend so much on the general income, which was more or less subject to fluctuation. He concluded by expressing the hope that they might have the pleasure of seeing Mr. Bartlett at some of the meetings, as he would no doubt be interested in seeing for himself how the business of the Institution was carried on. Mr. Stanger seconded the resolution, which was carried. Mr. C. Brown replying on behalf of Mr. Aird and the other retiring officers. Officers for the present year were then elected, and in reference to which the treasurer (Mr. Brooks) spoke in complimentary terms of Mr. Bartlett, who headed the list, and also referred to the valuable services rendered by some of the members who had already served and whose names were included amongst those re-elected.

## LOW SIDE WINDOWS IN CHURCHES.

THE original use of low side windows in churches, one of the most widely controverted points in ecclesiology, forms the subject of a "Conference" in the *Antiquary* for

March, in which several architects and antiquarianstake part. Their opinions differ greatly, as might be expected. Mr. C. E. Ponting, F.S.A., of Marlborough, disbelieves in the theory that these windows were made to allow the priest to communicate with lepers; but thinks that the principal object was for the sacristan standing inside to ring the bell at Mass at the open window. His reasons are that the low side windows never exist together with an outside bellcote, and that where a village or group of houses exists on one side only of a church, the low window is always placed on that side. This hypothesis also accounts for the use of so many so-called "squints," which do not command a view of the high altar from side chapels or transepts. Where these side windows are found, as at Stanford-le-Hope, St. Mary's, Guildford, and Bishops Cannings, in the west wall of the nave or aisles, they may have been for confession, or for worship outside the church. Mr. J. Lewis André contends that they were used for confessional purposes, and points out that while some, like that at Sherringham, have a coeval stone seat provided inside, all the examples of these windows are prior to the introduction, in the Decorated period, of the shriving pew. The Rev. C. R. Manning, F.S.A., admits that scarcely any documentary evidence exists as to their use, and considers, from the diversity of their position, that they served more than one purpose. He makes an amusing confession that in the *Gentleman's Magazine* for 1865 he described an example in the north aisle of Weybread Church, Suffolk, which, he was afterwards informed by the late Mr. R. M. Phipson, of Norwich, was a feature entirely of that architect's own production! The Rev. Dr. J. Charles Cox, F.S.A., says he has been compelled by further study of the leper question in England to abandon the theory he formerly held that these are "leper windows"; he now considers that the Sanctus-bell theory is the only one that will afford satisfactory explanation of over 90 per cent. of known examples. Mr. Temple Moore, of Hampstead, describes a 15th-century example recently uncovered by him at Winestead Church, Yorks; and Mr. J. F. Fowler, F.S.A., of Durham, gives a list of fourteen examples examined by himself. Mr. Charles Lynam, of Stoke-on-Trent, suggests that a complete list of all known examples should be put on record, and, as a beginning, describes in full detail the one at Church Eaton, Staffs. Like Mr. Fowler, he propounds no theory on the subject.

## BOOKS RECEIVED.

*Electrical Engineering for Artisans and Students*, by W. SLINGO, Principal of the Telegraphists' School of Science, and A. BROOKER, instructor in electrical engineering at the Telegraphists' School of Science (London: Longmans, Green, and Co.), is a very comprehensive manual, covering the whole field of electric lighting, and well adapted for students. The work embraces the branches prescribed in the syllabus of the City and Guilds Technical Institute. The authors have met the requirements in an apparently satisfactory manner, and have given particular attention to the practical part of the subject of lighting, and the wants of those engaged as engineers on various services. To this end the theory of the science has been slightly dealt with, but sufficiently for the requirements of the practical engineer. The authors have distinguished between the three kinds of electrical phenomena, the static, or frictional, the dynamic, and magnetic, and have shown that magnetism is the consequence of dynamic electricity, rather than a distinct law, or series of laws. Particular attention is given to the units, the measurement of current strength and resistance, and various types of dynamo-electric machines, these being all illustrated by carefully prepared wood engravings, also to the "lines of force" which cannot be too clearly or strongly impressed on the mind of the practical electrician. The various kinds of apparatus used in electric lighting and in an installation equipment, and the various arc and incandescent lamps, are described and illustrated. The book is a capital introduction for the young engineer.—*Spon's Architects' and Builders' Price Book*, 1890, edited by W. YOUNG, architect (London: E. and F. N. Spon, Strand). This well printed and neatly got up work has reached the 17th edition, and its publishers have added many useful memoranda, and made it a pocket as well

as a price book. The alphabetical arrangement of the memoranda, which precede the builders' prices, is a decided merit of this compilation, as it enables the architect or builder to turn to information at once. Amongst the subjects treated are ancient lights, and tables of angular width and height, approximate cost per cubic foot of building; arches, their thickness and abutment, thickness of walls for churches required by the Incorporated Society, seats, columns, girders, drains, surveying, valuation of property, and various formulæ and tables of general interest. We cordially recommend it to the profession.

#### FRESCO CEMENT.

ON Wednesday, March 5th, Mr. Edwin Lucas read a paper before the Civil and Mechanical Engineers' Society (Mr. H. Adams in the chair) on a new medium for fresco painting, called "Fresco Cement."

The composition, invented by Mr. Kremeyer, consists largely of tufa, together with Portland cement and lime, and the patentee claims for it that, being hydraulic, unabsorptive, and acid proof, it is absolutely unaffected by the severest climate. The author gave a highly interesting résumé of the history of the art of fresco painting, and of the various methods employed by great Italian masters, by the modern German school, and by artists in this country, dwelling on the great difficulties with which votaries of the art had to contend, on the elaborate nature of the process required, and on the want of permanence in the

complete work. In illustration of the last defect, especially in our climate, he pointed to the fact that English artists had from the 12th century devoted great attention to works of this nature, and asked, "Where are those works now?" He then proceeded to quote a favourable report from Mr. H. Faija, M.I.C.E., who, moreover, tested the strength of specimens which had been immersed in water for 23 days. The average tensile strength of five specimens was found to be 312lb. per square inch. The paper concluded with a practical demonstration of the extreme simplicity of the process, by means of the portable fresco panels, which form a striking feature of the new invention.

#### NEW BANK AND HOUSE, EAST MOLESEY.

THIS view illustrates new banking premises, with house adjoining, at East Molesey, Surrey, for Messrs. T. Ashley and Co., bankers. It is built of red bricks, which were obtained from Canterbury. The stone used throughout the fronts is red Newbigging, of fine texture, the roofs being covered with red Broseley tiles. The buildings have been carried out under the superintendence of Mr. T. H. Nixon, architect, by Messrs. Wheatley and Son, of East Molesey, at a cost of £2,370, exclusive of bank fittings, which are of best Honduras mahogany.

The new museum at Hanley will be opened by the Princess Louise in May or June next.

#### COMPETITIONS.

LIVERPOOL.—Designs for the Plymouth-grove chapel have been submitted in limited competition, and the plans sent in by Mr. Robert Curwen, of London, have been chosen. The plan adopted is said to be very similar to the Ashbrook-road chapel, Sunderland, by the same architect. A nave-and-aisle arrangement is the leading feature of the design. Four plans were submitted, and no professional referee was engaged.

TONG.—The committee of the Tong Liberal Club have accepted the plans submitted in a limited competition by Messrs. Empsall and Clarkson, of Bradford, and the works are to be commenced without delay. In the basement are public slipper baths, heating chamber, store cellars, &c. The reading, committee, and club-rooms, and the curator's living apartments, are placed on the ground floor, the first floor being occupied by large billiard-room, card-room, lavatory, &c. The elevations are in the Queen Anne style, of simple design.

A travelling studentship of £50 is offered by the Painters' Company for the encouragement of the study of decorative painting. The studentship is open to competition by students between the age of 20 and 35 in any recognised school of art or other institution devoted to the study of applied art in any form, and situate within the limit of the larger Metropolitan postal area. The rules for the competition can be obtained from the clerk of the Painters' Company, Painters'-hall Little Trinity-lane, London, E.C.

CONTEMPORARY BRITISH ARCHITECTS — MANSIONS IN HAARLEM-ROAD, BROOK GREEN—ST. HILDA'S CHURCH, SUNDERLAND—INTERIOR OF THE "NEW TOMB" AT THEBES, B.C. 1700—DESIGN FOR A PUBLIC DAY SCHOOL FOR 400 BOYS.—PLYMOUTH ASYLUM.—HOUSES IN FRANKWELL, SHREWSBURY.

## OUR LITHOGRAPHIC ILLUSTRATIONS.

CONTEMPORARY BRITISH ARCHITECTS.

(See description on p. 326.)

DORDRECHT AND UTRECHT MANSIONS, HAARLEM-ROAD, BROOK-GREEN, W.

THESE and other blocks of residential flats have recently been erected in this road. Each flat contains two sitting-rooms, two or three bedrooms, kitchen, bath, and w.c., and a coal-cellar in the basement. A provision lift communicates from the tradesmen's entrance to each kitchen, and an asphalt tennis-court for the use of the tenants is provided at the back of the buildings. The rentals are from £40 to £70 a year for each flat, so it will be seen that, from a monetary standpoint, they compare favourably with eligible villas of an ordinary suburban type. The fronts are faced with red bricks, with Douling stone bands, Portland stone landings, and the roofs are tiled. The builders are Messrs. Leslie and Co., of Kensington, who have satisfactorily carried out the work, and the architects are Messrs. Lewen-Sharp and Arpin, of 3, Duke-street, Adelphi, W.C. These drawings were in last year's Royal Academy Exhibition. At an early day we shall give a view of Mechlin Mansion, with a plan.

ST. HILDA'S CHURCH, MILLFIELD, SUNDERLAND.

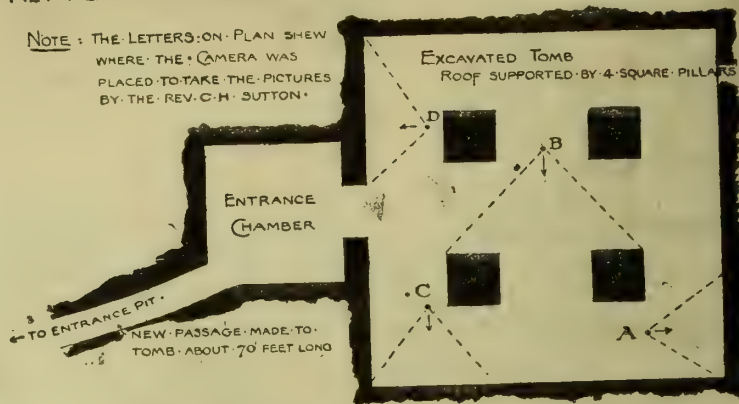

THE plan and interior view of St. Hilda's Church, Millfield, Sunderland, which we give, is that sent in competition in 1888, under the rebus device of a "Mill in a Field," by Hicks and Charlewood, of Newcastle-upon-Tyne, and finally accepted by the committee for adoption. The cost was then ascertained by a tender, and builders undertaking at about £3,000, the accommodation being calculated at 500 sittings. Some important changes have taken place in the district since that time, and it is now decided to build the church as a memorial to the late Bishop of Durham. If funds are forthcoming the church will be treated rather more handsomely, and a tower and spire will be added if possible. A change will be made in the interior design by substituting a chancel arch or some other internal break between the nave and chancel, in place of wood beam and cross shown in the sketch.

REPRESENTATIONS OF THE INTERIOR OF THE "NEW TOMB" AT THEBES, UPPER EGYPT.

THESE photo.-tints are from photographs taken by the Rev. C. H. Sutton, English Chaplain at Luxor, during last winter. They have been taken on Monckoven's dry plates by means of magnesium ribbon light. The tomb was one not generally shown previously to last winter to visitors to Thebes, the entrance being somewhat rough. It was shown to Mr. Sutton by an Arab, and the entrance he describes thus:—I was taken by my Arab to an opening in the ground, a well-like pit sunk some 15ft., and was told to

## KEY-PLAN TO ILLUSTRATION OF THE NEW TOMB AT THEBES.

NOTE: THE LETTERS ON PLAN SHOW WHERE THE CAMERA WAS PLACED TO TAKE THE PICTURES BY THE REV. C. H. SUTTON.

jump or drop down. At the bottom of the pit we found a tunnel about 3½ft. high running downwards into the hill above us. We had to crawl on hands and knees with our candles till we arrived in a small chamber half-filled with rubbish (probably about 8ft. square), from which was an entrance by a doorway some 4ft. high into the above-represented tomb. This second room was a much larger chamber, probably 20ft. square, with four square pillars left to support the roof when this chamber was excavated. The walls had all been coated with plaster about 2in. deep, to give a smooth surface; had then been toned with a light yellow colour, to form the ground for the paintings, the colours of which are chiefly blue, green, a chocolate-brown, and black. Seeing that the tomb was in excellent preservation, the paintings being as fresh in colour as when first put on, I ordered my guides to have the entrance improved, and decided to photograph it. This tomb last year became quickly a favourite one to visit, and it having no number, and not being mentioned in "Murray's Guide Book," it became known amongst the visitors and guides as the "New Tomb." The tomb is that of a private individual—a gentleman of some wealth and importance, living at Thebes in the XVIIIth dynasty, who seems to have belonged to the priestly caste, and to have been connected with the royal family of that date. In the right-hand top corner picture B we have a view taken across the tomb, and looking between the columns, see on the other wall a large part of the "Ritual of the Dead," with representation of the mummies, disembodied souls (a bird with human head), and figures representing the Resurrection. In order to get the painting on the roof on the same plate, it was necessary to throw the picture on the plate out of perspective. In the side aisles the roof has not been smoothed, but left with projections of 18in., and painted with vines and lotus flowers, giving these the appearance of hanging from the roof. These are shown in the top left-hand picture A; also the favourite pastime of this gentleman—i.e., to sit in a boat with his wife, under an awning, with a slave burning perfumes before them, while they are towed by another boat rowed by their slaves. The black patch is where at some time the plaster has been knocked off, and an attempt has been made to make another tunnel to find other tombs—perhaps in 1842, when this tomb seems to have been first opened. In the bottom right-hand picture D, which have the man, his wife, and a priest—possibly this is the marriage festival, the priest in the leopard skin ejecting water of life over them in two streams, from a sacred jar. In the lower left-hand picture C we have again the man and his wife, first sitting, then the wife standing and following her husband, to make a sacrifice to the gods. The paint is water-colour and easily damaged by water, which at times entered the tomb and washed out much of the painting of the chapter of the "Ritual of the Dead." A complete set of photographs of this and other tombs can be obtained from Messrs. Spooner and Co., in the Strand. We give a block plan showing the position of the camera when these photos were taken.

SOANE MEDALLION, 1890. FIRST MEDAL DESIGN. —A PUBLIC DAY-SCHOOL.

THE following were the conditions given: The school was to accommodate 400 boys on a corner site with a frontage to an important thoroughfare

of 140ft. and 100ft. to a side street. The main front was to face due west and no right of light on the north side. In scheming the plan the endeavour was to keep the classrooms as far as possible from the noise of the main street by placing them near the eastern boundary, to obtain left-hand light from the east or north in all cases to the classrooms, and to place the playground so as to get all the sun possible. The principal rooms are placed on the first and second floors; the ground floor being devoted to the school kitchen and offices, the caretaker's residence, the covered playground—which is placed under the classrooms—and to the gymnasium, a one-storied building, to the north, entered from the playground. This building has a wooden roof and ceiling to which the climbing ropes and poles could be fixed; it is lighted by windows placed high up in the wall, so as to give as much wall space as possible, and by skylights running the whole length of the room. The gymnasium has also a door connecting it immediately with one of the staircases, so that it can be reached from all floors in wet weather without going into the playground. The principal entrance is in the south-east corner of the playground, from which one ascends the main staircase to the first-floor. On arriving on this floor, immediately opposite the staircase is the assembly hall, which, if desired, can be divided into two classrooms by a revolving shutter. On the left is a corridor which gives access to six classrooms, and at the end of this corridor is a secondary staircase, which would be used on dismissing the school, and for exit to playground. At this end, and also by the principal staircase, are placed the lavatories, the masters' lavatories being placed on mezzanine floors, entered from the staircase. On the second floor is a dining room, connected with the kitchen on the ground floor by a lift, a master's room, school library, two classrooms, a drawing classroom, lighted from the top, a lecture room, and a chemical laboratory, with a chemical store above. The classrooms are arranged to be heated by Boyd's ventilating school grates, and the ventilation is by means of extract flues, which run between the ceiling and floor over the corridors, with branches to gratings in the ceilings, the fresh air being admitted through openings under the windows. In the elevations of the building, contrast of colour was intended to be obtained by using red bricks for the lower portion of the building, with rough cast, tinted a warm ochre above, and a red-tiled roof. The window frames to be painted white or cream colour, and the external shutters green. No stone was to be used in the elevations, all mouldings, &c., being in brick or cement. The upper part of gymnasium has a deep frieze, divided into panels by pilasters, in which are carved subjects representing the English athletic games. The clock face is also carved in brick, the subject being "Father Time delivering an old man to Justice and Death." We shall give a detail of this design at an early date. Its author is Mr. Francis W. Bedford. The second medal design was illustrated last week.

The Sheffield school board have intrusted Mr. C. J. Innocent, of that town, to prepare plans for a school to be erected in Gleadless-road, Heeley, for 1,200 children, the total cost not to exceed 6 per cent. beyond £8 per head. At the same meeting Messrs. Wightman, also of Sheffield, were instructed to prepare plans for a school to accommodate 1,200 children at Woodburn, at a like limitation of cost per head.

## WAYSIDE NOTES.

THE cantilever, albeit that that impressively-named aid to construction is none other than the humble bracket "writ large," has this week been exalted to the skies. Its apotheosis took place with the ceremony on the 4th inst., when the magnificent bridge that spans the Firth of Forth was "opened" by the Prince of Wales. "Wonderful things, these cantilevers," thinks John Bull; "marvellous to a degree!"—and the good man regrets that he didn't know of the cantilever and its ways long before A.D. 1890. Perhaps he would turn a deaf ear to the suggestion that he daily hangs his hat and coat on a cantilever. It might be a shock to him thus to learn how humble and simple, though, for that reason, how grand and noble, is the principle upon which his new bridge is constructed. To know that the central girders of the Forth Bridge depend from the extremities of the huge diamond-shaped structures of open steelwork as a coat hangs from a peg behind the door, may be, with some persons, to destroy much of the sentiment connected with the bridge, and induced largely by the employment of the term *cantilever*. Yet to those fitted to appreciate true grandeur and impressiveness, the very simplicity of the bracket principle constitutes the most noble feature in the Forth Bridge, and one that lies at the root of its imposing appearance. For all things are impressive in an inverse ratio to the amount of complication evidenced in their design and construction.

Still, persons have got it in their heads that the Forth Bridge is on the cantilever principle, and if they proudly proclaim to us the fact, and we strive to point out that the cantilever has nothing to do with the integral calculus, but is twin brother to the aforementioned hat-peg behind the door, they smile blandly, as though to say, "We know all about that." This is exasperating to a degree. But it is a state of things that may be expected to continue for some time in spite of sentences such as that in Tuesday's *Times*, explaining that "in architecture the cantilever is merely a bracket," and all the information which the engineers of the bridge have been at some pains to convey to the popular mind through the medium of magazines, &c. A cantilever bridge it is, and a cantilever bridge it will remain, and there is no reason why things should be not known by their right names; but it seems a pity that ignorance should be so rife as to the meaning of a simple word, and that a principle as old as the hills should be believed by the public to be some new patent automatic, compound, double-acting, triple-expanding system of construction.

As for the Forth Bridge itself, the world should be pretty familiar with its general appearance. It is evidently a structure that will give no small pleasure to the engineer and architect to behold. For my own part, I am anxious to see it in the flesh—or rather the steel—believing it to be the most creditable piece of engineering of its kind ever brought to a successful issue. That it will greatly influence the future of bridge-building there can be no doubt. It will probably lead to a still further abandonment of close web iron construction in favour of open steel-work. Irrespective of the employment of the cantilever principle, which will be a factor to influence future bridge-designing, the Forth Bridge should induce engineers to still further throw off the bonds of traditionary construction and make further progress in a knowledge of the true principles to be observed in the use of steel and iron for constructive purposes.

Passing over the Trent at Newark, by the Great Northern Railway, a month or so ago, I noticed a new bridge in course of construction, over the river, for railway purposes, which, though having nothing to do with the principle of the Forth Bridge, yet appeared to me to have been designed, in respect to the method of ties and struts, with a full knowledge of what had been done on the Forth. It will be a bold, handsome bridge, judging by what I could see from the train, the designer having, if I remember correctly, broken away from the commonplace type of bridge of this class. With an exhibition of a desire for economy in metal, with superior evidence of knowledge of the laws of strains, and the lessons of past experience, engineering iron and steel construction improve in appearance. It has been said of Southwark

Bridge that there is so much metal employed in its construction, that it would pay a contractor to take it down and rebuild it. Since the time when this unlovely structure was erected weight of metal has decreased and scientific construction improved, and the result has been, in structures like bridges, a vast improvement in appearance. And I think now we are beginning to see that the evidence of suitability to end in view goes far to produce comeliness in the works of an engineer, either mechanical or civil. Directly the engineer begins to stick on cornices, mouldings, and the like for their own sake he goes wrong, and produces abortions. This appears most markedly in machinery. To me a fine locomotive is a "thing of beauty and a joy for ever," and I have invariably found the most pleasing to the eye are those that have been designed in a straightforward, honest manner, with regard only to suitability to a peculiar purpose, without striving for effect other than that naturally produced by necessary features, and without added "ornament" other than rows of rivets, clusters of bolt-heads, and the sheen of bright, polished metal.

Is Registration desirable? Well, not if the pig-sticking class of "architects" can be persuaded to confine their attention to competitions such as that hailing from the Governors of the Ashton-in-Makerfield Grammar School, who invite plans and specifications, with sections and elevations, and offer a premium of ten pounds, the said glorious premium to buy the plans outright, and to be pocketed by the muchly successful architect with feelings of gratefulness towards the Ashton-in-Makerfield Grammar School Governors. This is a tall order. I wish the governors would not receive a single plan. They, of course, won't receive anything worth having, not even for ten pounds; but the advertisement, as it appeared prominently in your columns last week, is one of the most barefaced pieces of impudence that it has been my pleasure to notice in recent years.

It is not so much the ten pounds; ten pounds is often now offered for a premium for a considerable piece of designing. Indeed, one feels some surprise at the liberality of the sum. Will the governors award the £10 all at once? It would be safer, I think, for them to let the fortunate architect have the money by instalments. Or, as they doubtless are aware of the responsibility they incur by placing a whole £10 note in one architect's hands all of a sudden, they would do well to invest it for him in some good local industrial concern, and let him have the interest. The reader knows that I have always taken great interest in the welfare of competition inaugurators. My sympathies are now with the governors of the Ashton-in-Makerfield Grammar School, and I do not wish them to do themselves harm by incautious dealings with a £10 note. They should remember, as I have said, the responsibility that attaches to the awarding of this premium in one lump sum to the architect who will be indebted to their kindness for the prize. They must take care that, if sent by cheque, the cheque is properly crossed, and, if I might advise, it would be as well to register the letter. In addition to the architect's formal receipt, I would also advise the governors to get the accompanying letter stamped with a sixpenny stamp at Somerset House, though, as they do say that "sixpence saved is sixpence earned," perhaps the governors may deem it an undesirable expense. If no reply from architect by return of post to that by which cheque was forwarded, the governors should wire up at once, and continue wiring up steadily till reply comes. If no reply to wires, it may be safely concluded that excitement on the part of the architect on receiving the premium has had fatal results. It is in view of this contingency that I have advised the governors to seriously think of the advisability of sending up the £10 by instalments. Say £1 per week, and don't forget to cross the postal orders "and Co.," also see that the letters are duly registered.

GOTH.

In order that a record of the number of visitors ascending the Monument may be kept, the City Architect (Mr. Alexander Peebles) has instructed Messrs. Le Grand and Sutcliffe, of London, to erect a set of Norton's turnstiles for this purpose. The alterations in the entrance way are being proceeded with.

## PLYMOUTH ASYLUM.

THE asylum here illustrated is for the county borough of Plymouth, and is for 200 patients, but in anticipation of future extension the administrative portion of the building is adapted for a larger number. It is being erected on a commanding site in the parish of Ugborough, on the borders of Dartmoor. Excellent stone for the building is quarried on the estate, and the masonry dressings are of limestone, brick, Portland and Bath stone. The chapel is in the Early English style. Messrs. Hine and Odgers, Plymouth, are the architects, and Messrs. Pethick Brothers, of that town, the contractors, the amount of the contract being £34,544. Mr. W. Smith is clerk of the works. The Mayor, Alderman Waring, Chairman of the Plymouth Justices, laid the foundation stone in 1888, and it is expected the building will be ready for occupation in the spring of next year.

## OLD HOUSES, FRANKWELL, SHREWSBURY.

THE accompanying illustration represents a block of four houses, sketched during a visit to Salop last year. The houses lie in one of the lowest thoroughfares of Shrewsbury, and are approached from the old "Welsh Bridge." They are rather mutilated specimens of the old domestic work so characteristic of Shropshire. The whole of the ground-floor windows and doors are modern abortions, as also the bay windows and cornice under, in right-hand block. Owing to the ruthless ambition of one or two enterprising local tradesmen, several excellent specimens of this period have been replaced by "Victorian" examples. G. P. BANKART.

## CHIPS.

The town council of Romsey have appointed Mr. John Crook, at present sanitary inspector, as borough surveyor.

St. Stephen's School Church, Ryecroft, Walsall, was opened on Thursday afternoon, Feb. 27th. The building is situate at the corner of Proffitt-street, and is Gothic in style, comprising a nave, 38ft. by 25ft., with chancel 13ft. by 10ft., a schoolroom 20ft. by 35ft., vestry, and kitchen, and the whole is surmounted by a bell-turret. The materials used externally are red brick with stone arches and dressings, and tiles for the roof; and the internal fittings are of pitch pine, varnished. The building was carried out by Messrs. Dorset and Sons, of Cradley Heath, from designs by Mr. H. E. Laverder, of Walsall, and the cost, inclusive of fittings, will be about £700.

A new pier has been commenced this week at Falmouth, for the purpose of a submarine mining establishment for the War Office authorities. The site is near the old Manor House at Arwenack, and Mr. Hill, of Westminster, has taken the contract for construction.

Mr. William Thompson, architect and quarry owner, of Grantham, died at his residence, Grove House, Avenue-road, in that town, on Friday, aged 75 years.

The Wesleyan chapel at Sevenoaks was reopened on Wednesday week after alteration and improvement carried out by Mr. W. Wiltshire from plans by Mr. T. Potter.

The St. Helen's and Haydock lines of tramways were officially inspected last week by General Hutchinson on behalf of the Board of Trade, who was accompanied by the engineer, Mr. J. Waugh, C.E. The lines will be worked by steam power.

The bust of Lord Farnborough, better known as Sir Erskine May, was unveiled in the library of the House of Commons by the Speaker yesterday (Thursday).

The 47th annual congress of the British Archaeological Association will be opened at Oxford on Monday, the 7th July, by an inaugural address by the president, the Earl of Carnarvon.

The chancel of the parish church of Newport, Salop, is about to be restored and a new vestry added, from plans prepared by Mr. Morton.

The chancel of St. Mary's Church, Stamford, is being restored and decorated. Mr. J. D. Sedding is the architect, and Messrs. Charles Trask and Son, of Norton-sub-Hamdon, Somerset, are the contractors.

The death of Ernest Chesneau, the French art critic, took place on the 21st ult. In this country he was known as the author of "The English School of Painting," the preface to which was written by Mr. Ruskin, and also for his work on the Dutch school of painting.

## Building Intelligence.

**BOTCHERBY, NEAR CARLISLE.**—A mission church is now in course of erection to provide for the inhabitants of the village of Botcherby, near Carlisle. Local red bricks are being used for the walls, and the roofs will be covered with Welsh slates, except the roofs of porch and turret, which will be covered with local red tiles. The carpenter's work will be of Baltic white wood, and the joiner's work of pitch-pine. The walls internally and the ceilings will be plastered. The roof principals, which are to be dressed and moulded, will show below the ceiling of church. Accommodation will be provided for 173 adults. The cost, exclusive of pewing and the boundary walling, will be about £500. The principal contractors are Mr. James Metcalfe, builder, and Mr. J. Reed, joiner. The architect is Mr. H. Higginson, M.S.A., Carlisle.

**BRADFORD.**—The new Midland Station, in Forster-square, was opened on Monday. The buildings, which have a façade of 300ft., are in style Italian Renaissance. The hotel, which is five stories in height, is situated at the Cheapside end, and extends for some 150ft. along that thoroughfare; its main frontage is in Kirkgate. A striking and pleasing feature of the Kirkgate front is a tower, octagonal in form, and surmounted by a dome and finial. This tower rises from a square porch, with fluted and carved pillars, forming the main entrance, and leading up into the grand hall, about 33ft. square, from which access is obtained to the corridors and staircases. The exterior walls of the building are of local ashlar, with brick backing. The lower portion of the masonry is rusticated, but above it is polished. The roof is of Mansard form, and has a covering of Westmoreland slate. The outer walls of the station buildings is in harmony with the masonry of the hotel. Its treatment is generally plain, but the façade is broken by pilasters, circular-headed window spaces, and eleven entrances, all fitted with gates of wrought iron, comparatively light in structure, and ornately treated, and supplied by Messrs. Hart, Son, and Peard, of London and Birmingham. The three waiting and booking halls are each 45ft. by 26ft. They are tiled to the ceiling in tones of brown and buff. The first-class refreshment-room has a tiled dado, the remaining space to the top being similarly treated in a lighter shade. In the third-class refreshment-room the dado is of wood, the remaining wall space being papered. The floors are of random mosaic work. The internal width of the station is 174ft., and the inclosing walls are spanned by a glass roof, formed of a series of bays which take the shape of an inverted V. The space is inclosed by two spans, the central weight being borne by cast-iron columns, placed at intervals of 60ft. The bays rest upon wrought-iron Warren girders, which cross the station from wall to wall, the upper part being concealed by the glass work of the roof. The length of the glass roof is 450ft., and as School-street Bridge crosses the line at one end of the roof, the remainder of the platforms are protected by awnings supported on columns at a lower elevation. The length of the central platform is 752ft. The buildings have been constructed under the personal supervision of the architect, Mr. C. Trubshaw, of Derby, assisted by the resident clerks of works, Mr. Austin and Mr. Hardy. The main contractors are Messrs. Brown and Sons, of Salford; but Messrs. Butler and Co., of Stanningley, have done the larger part of the station roof and the platform awnings. As sub-contractor, the mason-work has been done by Mr. C. Murgatroyd, of Idle, including the flagging of platforms; the painting and decorating by Mr. Higginbottom, of Idle. Messrs. Cordingley and Son, of Bradford, have done the plastering and concreting. The stone carving has been executed by Mr. H. Frith, of Gloucester. The large clock over the booking-hall is by Messrs. Potts and Son, of Leeds.

**CROMER.**—A new hotel is about to be erected here. The hotel will contain a large dining-hall and drawing-room, also reading, writing, smoking, and billiard rooms on the ground floor, all on the sea front, besides eight private sitting-rooms and upwards of 60 bedrooms, the greater part having a sea view. A passenger lift will be provided to all the floors. There will be the usual kitchen office and other accommodation. A tennis lawn will be laid out, and good stabling provided in

the hotel grounds. Building operations commence at once by Messrs. J. Youngs and Son, contractors, of Norwich. The plans were prepared by Mr. George J. Skipper, F.R.I.B.A., architect, of Norwich, under whose superintendence the whole of the works will be carried out. The hotel will be finished in the spring of next year, ready for the season.

**PAIGNTON.**—The Cottage Hospital has just been completed in Church-street at the cost of the Messrs. Singer. Plans were invited, for which a dozen architects competed, and of these three were selected for final consideration. Of these the first received 13 votes, the second 12, and the third 11. Nos. 1 and 3 turned out to be those of Mr. G. Soudon Bridgman, whose design has been carried out by Mr. Henry Webber, builder, of Paignton, his tender being accepted at £1,825 10s. The building has been planned on the ward system, and is entirely contained on one floor. The entrance lobby leads into an operating room, and there is a special accident ward adjoining. On the other side of the corridor are two wards, one for male and one for females, each containing four beds and one cot. Between them are a nurse's room and a bathroom. The sanitary arrangements are in separate wings. The dispensary department has a separate entrance, and consists of waiting-room, consulting-room, dispensary, and offices for the surgeon. At the rear of the building is the administrative wing, containing kitchens and scullery, and over these a sitting-room and three bedrooms for matron and others. No drains enter the building. The external treatment is that of a cottage in the Domestic Gothic style. The whole of the walling is rock-work, jointed with red cement. The main coigns, strings, and arches are composed of Berkshire red bricks; a few of the dressings of the labels are of Ham Hill stone. The roofing and tile-hanging is also of Berkshire red tiles. The ceilings of the wards are waggon-headed, the timber of the principals and purlins showing. All the floors are laid with pitch-pine block flooring, laid in a herring-bone pattern, and the corridors and verandahs are laid with encaustic tiles.

**SOUTH KYME.**—The parish church was reopened on the 17th ult. by the Bishop of Lincoln. During the restoration, many points of interest were brought to light. Drawings were taken for future reference. The church was originally dedicated to All Saints, the monastic portion, the site of the foundations of which can easily be traced on the north of the church, being still called "Abbey Yard," were erected by Philip de Kyme in 1170, being enlarged by his son Simon. The church was re-erected in the 14th century, in the Flowing Decorated style, retaining the doorway of the Norman church. It was formerly a large cruciform building, divided into nave and south aisle by an arcade of cloistered columns, of which the western one remains. The tower was in the centre. The chancel used by the monks was destroyed, as well as the tower and transepts, in the 16th century. In 1805, the nave and aisle being decayed, the north side and the arches were taken down. Fourteen feet have now been added to the length of the church, making it as long as it was before the changes in 1805. The north wall has been taken down and rebuilt, and two traceried windows, each of two lights, inserted. The east wall was also taken down, rebuilt, and a five-light tracery window built, with blank tracery beneath. On the S.E. portion a new window has been opened out. The east window and the centre one on the south side are to be filled with stained glass. A new chancel screen has been erected 14ft. high, surmounted by a cross 8ft. high. Side screens have been built in the chancel, forming a sacristy on one side and an organ chamber on the other. A choir vestry has also been formed at the west end. The whole of the church has been re-seated, and among the new features are roof to chancel, oak lectern, and heating apparatus. The entire cost of the restorations and improvements is £1,600. The architect was Mr. C. H. Fowler, F.S.A., of Durham, the contractor being Mr. Bowman, of Stamford.

The students attending the Honours and Ordinaries Grade, Carpentry and Joinery Class, at the Heriot-Watt College, Edinburgh, to the number of eighty, visited Messrs. Brown Brothers' art furniture works in Caledonian-crescent, in that city, on Saturday afternoon, and were shown over the departments by Mr. Pendreich, the manager.

## ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

**ASSOCIATION OF SANITARY INSPECTORS.**—At a meeting of this association, held on Saturday at Carpenters' Hall, the council report on the status of sanitary inspectors was adopted. The report states that the conditions under which sanitary inspectors are appointed and discharge their duties are inimical to the interests of the public health, and that those conditions are due to the defective state of sanitary law. The council recommend that the influence of the association should be directed to secure the following amendments in sanitary law:—That every candidate for the position of sanitary inspector shall have a general knowledge of the building trades, and, in addition, shall possess a certificate in sanitary science; that sanitary inspectors shall be elected to a permanent tenure of office, and shall also be dismissible for misconduct or proved incompetence, with right of appeal to the Local Government Board; that it shall be the duty of sanitary inspectors to periodically inspect the dwellings of the district to which they are appointed, and to receive complaints of nuisances, and to serve notices forthwith requiring all necessary works to be done for the abatement of the nuisances, such notices to be as valid, if confirmed by the local authority, as if served by the authority's order; that in all appointments requiring the officer's whole time to be given to the duties of his office an adequate minimum salary shall be prescribed; and that the officers now variously named sanitary inspectors and inspectors of nuisances be designated sanitary inspectors.

**LIVERPOOL ARCHITECTURAL SOCIETY.**—At the meeting of this society held on Monday night, Mr. T. Mellard Reade in the chair, a paper was read by Mr. James M. Hay on the subject of the much-discussed panels by Mr. Stirling Lee in St. George's Hall. He pointed out that the only two panels executed were adversely criticised by the society as soon as they were fixed. In summing up, Mr. Hay said: The style of these panels is bad and out of keeping with the architecture. The conception and execution of the work are both defective. The nudity of the two figures is forced and unnatural, and in place of enhancing, diminishes the force of artistic expression. It betrays the influence of the realistic school that is doing so much in France to degrade both her literature and her art. The having the sculpture done on panels of white marble inlay, in place of on the stone impost, is bad architecturally, and an improper interference with the intention of Elmes, the architect who designed the edifice. We consider that it is an injustice to one of the finest buildings in this city that those panels should remain a patch and disfigurement on the face of it; that it is an injustice to the memory and fair fame of Elmes, and that it is an injustice to the people of Liverpool and an outrage on public decency, and we would respectfully ask the City Council to take immediate steps to have the offending panels removed and the stone imposts restored, before any further arrangement is entered into with any sculptor. Mr. J. A. Berrington seconded the motion, and Mr. J. L. Cook and others opposed it. After some discussion, it was decided not to take a vote, but leave the matter to the decision of the city council, who, as will be seen from a paragraph on p. 364, column 2, have accepted Mr. Rathbone's offer.

## SCHOOLS OF ART.

**METROPOLITAN DRAWING CLASSES.**—The Queen's prizes and certificates gained by the students attending the Metropolitan Drawing Classes were delivered to them at Carpenters' Hall, London-wall, on Tuesday week, by Sir John Lubbock, M.P. Mr. Banister Fletcher, the Master of the Carpenters' Company, presided. Before the distribution Mr. W. Busbridge, director and instructor of the classes, read his annual report. During the 24 years of the existence of the classes there has been a steady growth in numbers and success, and the present report spoke with undiminished satisfaction both with regard to the work (now carried on in 22 centres), the attendance of the students, and the satisfactory results of their labours, as tested by the Government examination. Since the opening of the classes no fewer than 14,000 students had passed through their course of instruction.

## TO CORRESPONDENTS.

We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

## TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 6d. (or 6dols. 90c. gold). To France or Belgium, £1 6s. 6d. (or 33fr. 90c.) To India (via Brindisi), £1 10s. 4d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 6d.

## ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

## SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING for TWENTY-FOUR WORDS, and Sixpence for every eight words after. All Situation Advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page advertisements and alterations in serial advertisements must reach the office by Tuesday Morning to secure insertion.

## NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XLII., XLVI., XLIX., L., LI., LIII., LVI., and LVII. may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—C. and Co., Ltd.—J. F.—G. N. Ry. Co.—H. and Co.—G. W. and Co.—W. and Co.—E. S.

J. H. M. (Too long; a shorter letter might have found room.)

## "BUILDING NEWS" DESIGNING CLUB.

DRAWINGS RECEIVED.—"Cleopatra," "Mac," "Parenchyma," "Pepper Arden," "Horseshoe," "I Try," "A. G." in a circle, "Finem Respite," "Nox," "Attempt," "Mercury," "Grafton," "West Anglian," "Menelaus," "White Star," "Niger," "Renaissance," "Lycidas," "Streona," "So and So," "Tyne" (no address nor name; send it), "Glancus," "Reference," and "White Wings," which has neither name nor address, and is too late.

## Correspondence.

## "THE ARCHITECTS' REGISTRATION BILL AGAIN."

To the Editor of the BUILDING NEWS.

SIR,—Such is the heading of a small notice in R.I.B.A. Journal No. 9. Very little comment thereon, except, I am glad to see, whoever wrote the article, that it is said the Council of R.I.B.A.—not members generally—object to the Bill. May I, who have not before written, I think, to the professional journals, say a few words on this important subject of Registration?

Mr. H. R. Gough, in your last, says 350 members of the Institute signed the petitions in favour of the Bill. I believe I am one of that number, and though I am very proud of the honour of being an A.R.I.B.A. by examination, and would uphold the Council of the Institute to the best of my little power in most matters, yet in the course they take with reference to this case I think they are making a mistake. I do certainly think that some of our worthy Fellows have not, to say the least of it, treated the supporters of the Bill in a very charitable manner. Why do those whom we Associates ought to look up to try to snub any effort that we think we may make for the general welfare of the profession? If they do not agree with us, their only course is to oppose; but I think they might do so in a more friendly way, and not try to sit upon us simply because we have a different opinion

from them. Let us at least agree to differ while each strives to do his duty. It may be that even the Council of the Institute are making a mistake, as the supporters of the Bill may be also; but, for my own part, as a provincial practitioner, I feel sure Registration is sorely needed.

I am sure our friends at Conduit-street cannot understand (not the general body of them, at least) what a provincial practice is like, and what a boon the protection of Registration would be both to the public at large and also the profession. Let them, therefore, allow that we may have some good reason for pressing this Bill, though I, as many others, most earnestly wish that the Institute had set the Bill going.

Now, I would suggest that all the Fellows and Associates who uphold the Bill should sign a distinct petition in its favour, the names of the petitioners being only members of the Institute; then these names, which I venture to think would be a good proportion of the whole members, would show to Parliament that the petition against the Bill submitted by the Council was far from being the unanimous voice of the Institute; and add to this the great number of other petitions submitted in favour, signed by other architects who are not members of the Institute, and I feel sure the door which has seemed so firmly locked and bolted will have a terrible blow, and, if not quite blown open by the first gust, we may next time add more names to our lists, and after patience the door may creak and then burst open, to the general benefit of the community and also of our own profession. Would not some influential member take the matter up? I should be most happy to do my part, and get any members' signatures I could. Apologising for taking up so much of your valuable space,—I am, &c., JOSEPH LAVENDER, A.R.I.B.A.

Wolverhampton, March 4.

SIR,—A few days ago there appeared in the *Construction Moderne* an article by Monsieur Planat discussing the diploma, and also the registration of architects, subjects that are drawing very much attention in France, as in England, at the moment amongst architectural circles. As it might be interesting to your readers to know what is thought of the subject here, may I trespass on your valuable space, and give a few freely translated extracts from the above-mentioned discussion? Naturally a certain amount of what Monsieur Planat says does not apply to the case in England, where the system of architectural training is so different from that recognised in France. In this country the system of apprenticeship to an architect is very little known. When a young man decides to enter the profession, he enters a special school, follows the courses of lectures, and works at drawing and designing in one of the "ateliers," or studios, in connection with the school, and endowed likewise by the State. If he lives in the provinces, he finds it best, and, indeed, almost a necessity, to go to the central "Ecole des Beaux Arts" at Paris, and there pass four or five years in learning his profession. Here, if his parents are not rich, he lives the more or less vagabond life and participates the joys and sorrows of a student. Before entering the "school" he has to pass a moderately difficult entrance examination, for which he has generally prepared himself at an elementary school. This examination exacts a certain skill in drawing from the cast, modelling in clay, and a sufficient knowledge of the Five Orders to make a perfectly correct Classical design with details to scale. If he satisfies in these, he is allowed to proceed with the more difficult examination of mathematics, geometry, descriptive and plane, &c., and also the general history of architecture. If he manages to get through this, he is admitted to a place in the school as a "nouveau," or freshman. He enters the school atelier or studio of his preference, and occupies his time in designing and colouring from programmes given out from time to time, of classical studies of the Orders and details. To help him, he may obtain any information he desires amongst the books of a large, well-stocked library belonging to the school. He has the best professors, and some of the ablest architects come round the studios two or three times a week in order to correct and advise. When he is proficient in the orders, and has gained a certain number of values or marks in the monthly "concours," he has a remove to the second class. There he competes with his fellow students, designing from simple programmes given out once a month. By a certain day each month the students have to give up their

drawings, correctly drawn and coloured, and mounted on stretchers provided by the studio. In the intervals of his atelier work he follows lectures given by able professors on construction, geometry, chemistry, perspective, &c. When he has obtained a certain number of values in all these subjects, and a certain number of mentions for his drawings, the student is allowed to enter the first class. Here the programmes given are more complicated, and the drawings, "rendus" or coloured, are often the most artistic. The student now follows the courses of lectures on construction, &c., more carefully. If he is a hard worker, he finds a place in an architect's office, where he works in the intervals of studio study, and is enabled to follow more efficiently the practical side of his profession, at the same time earning something; the payment in the offices is generally by the hour for Beaux Arts students, and varies from one franc to two francs fifty per hour. If by his drawings in the studio he shows himself possessed of a certain amount of talent, he is allowed to enter in competition for the "Grand Prix de Rome," the winner of which obtains a "bourse" for three years' study at Rome. Those who do not compete for this prize study closely their construction, and prepare to pass the examination for the diploma. In this test they are allowed to choose their own design for a large building, and have to furnish well-studied drawings, as well as constructional details; a *viva voce* examination on construction, &c., of the design has to be gone through. Those who satisfy the examiners are granted Government diplomas, and may now make a start in their profession. Naturally the studio training develops very highly the artistic ability and fertility of design in the student. As far as practical work goes, he can only form his ideas from the lectures on the subject, unless he is hard worker enough to follow for part of his time the practical work at an architect's office. To "faire la place," as work at an office is called, and also follow his work at the school is difficult, the student often working all night as the day for the giving up of his designs draws near. The constant mingling in the studio with others who are following up the same programmes, and with painters and sculptors in the school, develops most artistic men, who can produce the most artistically designed and coloured drawings. This artistic training the English student, unfortunately, often lacks, generally having to occupy himself in an office only with details, &c., specialists often being employed when any artistic drawings for a competition is required. Certainly he has the advantage in practical knowledge often lacking in the young French student, the latter, however, taking the palm in artistic designing and colouring.

Apropos of the diploma, Monsieur Planat says: "I fancy that it would be well to ask ourselves first what is a diploma and what is its end, what is its value, and whence comes its authority if it has any. There exist two kinds of diploma; some a veritable privilege, conferring an exclusive monopoly in the exercise of a profession; others are only a grade, a certificate of studies made and of knowledge acquired, putting before the public the superiority of the person diplomaed. The results are very different in the two cases; but one will notice directly that in the one case as in the other, monopoly, or simple certificate, the diploma is always granted by the State. This is because a diploma is only valuable when it is a guarantee or acknowledgment of competence on the part of the diplomaed, and up to the present time the State only offers this guarantee in a sufficient degree. If one looks for the most complete example of an exclusive professional diploma, it is in the medical profession that it is found. Generally, apprenticeship to a profession exacts a course of studies carefully followed; the acquisition of technical knowledge as a result of these studies; and, lastly, a certain practical experience." These facts, then, the grade or diploma try to guarantee. In the case of the medical profession this guarantee is complete; partial examinations during the course of the studies, definitive examinations questioning the profit the candidate has made of his studies, and for practical experience—that which other schools rarely give, and have hardly the right to exact—the "internat and externat." The teaching is here followed to the end, complete; complete likewise is the guarantee in the shape of a diploma. Coming to architecture, the first question to ask oneself will be this, Can the profession be limited, can it and ought it to

remain open to all? This is one of the most important questions, one of those that more than one would like to see answered in the negative sense, for it would be advantageous to him to exclude the greatest possible number of competitors.

Is this possible? At the first sight analogies seem to indicate the contrary. Does it come to anybody's thoughts to reduce the number of painters, sculptors, and literary men, or to impose examinations or competitions on the *début* of their career? In fact, every profession which is at the service of the public is free, and lawfully free. On what article of the State code would one rest to interdict a citizen the exercise of a profession which suits him?

"But what about the doctors?" you will say.

Without doubt there we find an exception probably unique; but an exception made on very powerful reasons. Medicine in the hands of an incompetent man is one of the most dangerous professions; a wrong prescription might result in death. The State has only sought to defend the interest of the public, and not that of the doctors, by forbidding a free exercise of medicine.

Touching the same exclusion for architecture, I see very well the interest on the architect's side, but not the general interest of the public (*sic*), and consequently the legitimate intervention of the State. Can anyone say that the free exercise of architecture is equally a public danger? This would truly be exaggerated; a badly planned building or badly studied façade does not necessarily occasion anyone's death. There may be a certain inconvenience in employing an unskilful architect, but rarely a grave danger. In every case this is not a diploma given with the innumerable guarantees surrounding the medical profession—with its several examinations, its practice organised and pursued during a number of years—this is not a diploma which would put one on guard against the danger. The State prescribes its code of architect's responsibility, recalling—that which he may sometimes forget—that the contractor is not the only constructor of the work, and this is all the State has the right to do.

If we were to start in this manner, how far would we have to go? where would one stop? The diplomaed and patentees only could be railway machinists, miners, theatre directors, contractors, carpenters, even journalists, so many professions where a lack of skill or inexperience could produce grave consequences. Can we imagine the State interposing its veto on the entrance of each of these careers?

Thus monopoly seems to me impossible to establish; it is, then, useless to discuss the advantages or the inconveniences. But what we can do is to create grades, honourable distinctions, in order to separate the *élite* from the *négligé*.

Let us see what exists at present. The complete official teaching is given by the State in an establishment nearly unique. Formerly the only guarantee of studies was the "Prix de Rome"; since, there has been created a diploma given on special examinations, and a series of rewards or values obtained during the course of the studies. There exists at Lyon and at Lille a school of architecture, but Paris only awards the diploma.

The "Prix de Rome" guaranteed especially the artistic ability of the "laureat," and his artistic sentiments a certain idea of classical arrangement somewhat conventional, and his skill as a draughtsman; the diploma, when it is quite what it ought to be, guarantees his technical knowledge. All this can be ascertained by means of examinations, and this is what makes the special value of the diploma. As to practical skill, we cannot exact this from the School of Beaux Arts any more than from any other school, an examination controlling that which it cannot teach. The "school" is, without doubt, the most favourable centre for artistic education, lessons by distinguished masters, the constant life at the atelier or studio, the contact with painters and sculptors, the mutual exchange of ideas, comparisons, and reflections, are the right conditions necessary to form that which is called taste, at the same time developing the fertility of artistic design. Thus the studies made at the "Ecole" are, say what we may, a recommendation in favour of the artistic talent of an architect. It may be no more, but it is no less.

The young diplomaed—and they are still young—have ambition and the future before them. They have acquired a title, and they wish to use it. One can easily guess that the end pursued

by them is to become polytechnicians in architecture. I understand that they wish to induce the State to reserve its works for the architects instructed by itself, examined, and recompensed by it, as it does for engineers come from its special schools. It is not difficult to foresee that in the order of things this end will be obtained some day or other. Monsieur Planat proceeds to say, that the State should look to see if a single "school" at Paris awarding the diploma suffices for all needs, and if the necessity of living in the capital for several years is not of itself a natural obstacle to the free access to the profession, and if it is not necessary to create new departmental schools. Then he asks if in the case of departmental schools or societies enabled to grant a diploma to those who have not studied at the "Ecole" at Paris the difficulties and inconveniences are not great. In the case of a provincial architect, having passed the student phase and well entered on his career, would he not feel a certain constraint in having to come before his fellow architects and ask them to give him the baptism of the diploma? It would be absurd for him to have to come before them and give on the blackboard a *résumé* of the Five Orders; or, as this system is not convenient, let us judge the competence of the candidate according to the buildings he has erected. Let us look at the consequences: when an architect may have shown proof of his skill by some important building, and so acquired authority and renown, he will be allowed to present himself, and the diploma will be given him. What! to establish what the world already knows, that the candidate is an architect worthy of the name? To what end would the certificate serve? It is not generally at the end of one's career that a certificate of capacity is necessary. It is at the *début* that it is desired.

Now, if a *débutant* presents himself, it is naturally he who would claim the diploma rather than a man who has made his mark, and who has furnished his proofs, and has no longer need of a vignette parchment to put in a frame; he would not have behind him any examples to show. To decide as to his competence, to put a light on the extent of his knowledge, to what would we have then recourse? To the inevitable blackboard in the presence of two or three *confrères*, more or less benevolent to the new-comer. I believe that it is not necessary to insist any longer on these strange contradictions; a diploma is needed and is granted on leaving the "Ecole," later it is too late.

This, then, is the state of affairs and general opinion in regard to the diploma and registration of the architectural profession in France; how far it applies to the system of training in England, I leave to others for the present to judge.—I am, &c., ARTHUR J. VYE PARMINTER.

73, Rue Nationale, Lille, March 1.

SIR,—Kindly allow me to correct an error which appears in my letter in last week's issue. In the fourth line from the top of p. 328 are the words, "if the three hundred architects who gave their written approval of the principles involved." This should read, "if the *thirteen hundred* architects," &c.; or, to be more precise, I believe the exact number was 1,287; and of members of the Institute, "three hundred and fifty" should read 343.—I am, &c., HUGH ROUMIEU GOUGH.

Carlton Chambers, 12, Regent-street, London, S.W., March 3.

#### A MARKET COMPETITION (!) AT BILSTON, STAFFS.—AN EXPOSE.

SIR,—I am compelled, in justice to myself and to the architectural profession generally, to draw the attention of the readers of your valuable paper to the most unsatisfactory way in which the above competition (?) has been arranged. I had hoped the matter would have been made known before this by the Press; but as the worthy representatives of the Fourth Estate were carefully excluded from the meetings of the Commissioners of Bilston, the affair might have passed into the realms of oblivion had it not been for the existence of your humble servant.

I will explain the particulars of the case as briefly as possible.

A few weeks ago an advertisement was inserted in the Bilston paper, asking for plans, specifications, and tenders for a covered market for the Commissioners of that town, and stating that these plans, &c., must be sent to the clerk *not later* than the 17th of February; the total cost not to

exceed £3,000. Believing that I should receive fair-play (alas! what has become of it lately?), I submitted plans, &c., and also a tender from a responsible builder, for the carrying out of the work for the price mentioned.

Now comes the revelation: At the committee meeting on the evening following that on which the plans were to be received the time was *extended* a week to one competitor, who expressed his inability to have his plans in at the time stipulated in the advertisement.

The meeting, therefore, stood adjourned until the following week, no notification of an extension being sent to the other competitors. The meeting took place, the plans sent in a week after the appointed time were approved, although to carry them into execution would take a sum of money far in excess of that named by the commissioners!

Now, Sir, I venture to believe, and I am sure you will agree with the belief, that the extension of the time to one competitor was a gross injustice to the others, giving him a manifestly unfair advantage.

I maintain that the commissioners, having stated certain conditions in their advertisement, were morally bound to keep to them, and by doing so would have avoided even the semblance of unfairness and partiality.

Is not this a case for inquiry for the R.I.B.A. or the S.A.? I think it should be.—I am, &c., S. HENRY EACHUS.

Bank Buildings, Lichfield-street,  
Wolverhampton, March 5.

#### ZINC CEILINGS, &c.

SIR,—Referring to your article in last week's issue, there is a splendid ornamental zinc ceiling at the Theatre Royal, Malta. It was made in London, and, I believe, Holden and Co., of Westminster, did it. If so, perhaps they will give us some information on the subject, as well as about any others they may have executed.—I am, &c., INQUISITIVE.

#### ERRATA—TENDERS.

SIR,—I will thank you to correct a serious error in amount of my tender on Friday last.

For stable additions, &c., at Walton-on-Thames, E. J. Ingram should be £683, and not £863.—I am, &c., E. J. INGRAM.

Hersham-road, Walton-on-Thames, March 5.

#### CHIPS.

The new Kendray Fever Hospital, at Barnsley, presented by Mrs. Lambert, of London, was opened on Friday. It is situated on the top of Measborough-hill, a short distance from the town, and consists of three separate blocks, administrative block, the isolation block, and the smallpox block. There is accommodation for about 20 patients. The hospital was erected from plans of Messrs. Morley and Woodhouse, of Barnsley, at a cost of £5,000, the site being provided by the Corporation at a cost of £2,300.

The Council of the Sanitary Institute of Great Britain have accepted an invitation from the town council of Brighton to hold the autumn congress and health exhibition in that town in September next.

The Falvey Memorial Committee met at Southampton last week and decided, as part of the memento, to commission Mr. J. Milo Griffiths, R.C.A., to execute a bust in marble to be placed in the Free Library of Southampton.

The Norfolk County Council have decided to divide the western division of the county into five sections, and to appoint a surveyor for each, at a salary of £100, each individual selected to provide his own horse and cart or other means for travelling over his district. For the five offices there were over 160 applicants from all parts of the kingdom. The following were the successful candidates:—Mr. E. Johnson, Brighton; Mr. J. E. Haynes, Southampton; Mr. J. W. Shaw, West Baildon, Newcastle-on-Tyne; Mr. A. H. Carrell, Havant; and Mr. James Kennedy, Alhwick.

The members of the Scottish Liberal Club have taken possession this week of their new premises, 109 and 110, Princes-street, Edinburgh. Formerly the Palace Hotel, the building, acquired last May, has been since that time in the hands of tradesmen, carrying out alterations designed by Messrs. Kinnear and Peddie to fit it for the requirements of the club. Alterations have been made upon the appearance of the street frontage by the introduction of large windows on the ground floor, and by the construction in front of these of a low balustrade, behind which light is obtained from a basement floor. The cost of the alterations has been £6,000.

# Intercommunication.

## QUESTIONS.

[10240.]—**Iron Gate for Shop.**—Will some reader kindly suggest a light iron gate for shop? Entrance doorway 4ft. 6in. wide. Is a "folding" gate to be recommended, and is it expensive?—MAIDEN CITY.

[10241.]—**Sundial.**—I have a sundial to fix in Mid-Cheshire. Will someone kindly tell me what "deviation of the compass" I must allow for in fixing the dial?—J. HOLLAND.

[10242.]—**Polygon.**—Would someone kindly inform me of the method of drawing a polygon whose sides shall be in a given ratio to each other?—for instance, a pentagon whose sides shall be in the ratio as 2, 4, 7, 9, and 12.—DARBY.

[10243.]—**Water-Mains.**—Will some kind reader give information relative to water-mains for town supply as to the following particulars? Would it be injudicious to lay water-mains in a marsh, or through river beds where spring tides flow over them? Is "bank casting" on slope inferior to "vertical casting" for water-mains? I am of opinion the former would be less liable to air-bubbles or the "spluttering" which might occur in the vertical casting—instance the filling of a bottle held vertically and on an incline.—WATER RATE.

[10244.]—**Are "Urinals" Water Closets?**—Are urinal basins flushed with a ½in. pipe "water-closets"? Could they be possibly construed as such? Our local magistrates say so.—C. Wakefield.

[10245.]—**Brass-Foundry.**—Would any reader who has had experience in planning of brass-foundry buildings kindly give advice as to the best kind of paving with which they should be floored? Would fireclay tiling 12in. by 12in. by 2in., laid in sand and grouted with cement, be efficient and durable?—BRASS.

[10246.]—**Mortuary.**—I am about to erect a town mortuary with post-mortem room adjoining, and shall be glad to have experienced opinion as to the suitability of a cement floor for such rooms, or if asphalt is advised. Glazed bricks are being used for walling throughout. Any hints on the subject from practical experience will be acceptable.—A.

## REPLIES.

[10233.]—**Who is Responsible?**—The clue use in the instructions in which it is stated that "it would be well for competitors to visit the church and satisfy themselves on all points" partially throws the responsibility on the competitors. Morally the committee who supplied the lithographed sheet of drawings showing the height of existing piers are at fault, especially as the piers were figured a certain height; but the successful architect is legally held responsible for not taking his own dimensions before his drawings were submitted to the builders. The committee invited a competition for plans for finishing the church, and the responsibility fell upon the successful architect. He undertook, in fact, to prepare drawings for the purpose of contract.—G. H. G.

[10238.]—**Boiler.**—It was contracted to "examine, clean out, and put in proper working order the large boiler" that was fitted in the cellar. This implies that the boiler, although dirty, was supposed to be serviceable, and that after being cleaned out the metal would be substantial enough for use. It will be observed that the word "repair" does not occur in above quotation. After being cleaned out it was found upon testing that the boiler was so worn out as to be "perfectly useless," and it was necessary to order a new boiler. Now, in these circumstances it was not the contractor's fault that the metal of the boiler was so worn out as to make the boiler "perfectly useless." If after being cleaned out it was so useless as that a new boiler had to be got, it seems to me that the owner of the old boiler is the party entitled to pay for the new boiler, and also for its fitting in. Supposing this large boiler was one with pipes attached to it, the words "put in proper working order" would mean that the contractor must see that the water came into the boiler properly, and it or the steam had free access out, so that after being cleaned the boiler would serve its purpose; but all this meant or implied that the old boiler was good enough for the purpose if cleaned. In my opinion the contractor is not liable to pay either for the new boiler or its fitting in, so far as we can judge from what is said on page 329.—W. P. BUCHAN.

[10234.]—**Radius of Arch.**—Let S = span, R = rise.

$$\frac{\left(\frac{1}{2}S^2 + R\right)}{2} \quad \text{J. C. H. S.}$$

[10237.]—**Moment of Inertia.**—Inertia is that inherent property in matter by which it tends to preserve a state of rest when at rest, and of uniform rectilinear motion when moving. "The moment of inertia," Rankine says, "of an independently small body or 'physical point' relatively to a given axis is the product of the mass of the body, or of some quantity proportional to the mass, such as weight, into the square of its perpendicular distance from the axis." By extension the term is applied to the product of any quantity, such as a volume or an area, into the square of the distance of the point to which that quantity relates from a given axis. A loaded beam resists fracture by the strength of its fibres. These are not all strained alike in each portion of the cross section; some are in compression, others in tension, the line separating the two classes being called the neutral axis, which for all practical purposes may be assumed to pass through the centre of gravity of the section. Those farthest from the neutral axis undergo the greatest strain. The resistance offered by the fibres is usually assumed to be in proportion to their area, amount of extension, and distance from the neutral axis; or, as the amount of extension is also in proportion to the distance from the neutral axis, the resistance of the fibres will be in proportion simply to their areas multiplied by the squares of their respective distances from the neutral axis. The sum of these results calculated for the whole section is the moment of

inertia of that section usually denoted by I. The strength of a beam to resist cross breaking is usually determined by the relation of the moment of the load to the moment of resistance. Let us assume a 6in. by 6in. by 1in. T iron beam supported at the ends, and loaded in the middle with a span of 10ft. Then the moment of the load is  $= \frac{W \times L}{4}$ , where W = the load, and L = the span.

The moment of resistance is  $\frac{MI}{N}$ , where M = the modulus of rupture or 6 K, the latter being a coefficient of fracture = 68 cwt. for wrought iron, I = moment of inertia, N = height of neutral axis from the farthest edge of the section. N and I may be found from the formula—

$$N = \frac{\Sigma B \Delta (H^2)}{2A} \quad I = \frac{\Sigma B \Delta (H^3)}{3} - AN^2$$

Where H = height of particles above lower edge of section (in this case they may be taken as 5in. and 6in. respectively), B = breadth of section at any height H (in this case 1in. and 6in. respectively).  $\Sigma$  and  $\Delta$ , of course, mean sum and difference.

$$A = \Sigma B \Delta H = 11$$

$$\therefore N = \frac{91}{22} = 4.136$$

$$I = \frac{671}{3} - 11 \times 4.136^2$$

$$I = 35.46$$

The moment of resistance is then  $\frac{6 \times 68 \times 35.46}{4.136}$ ; equating

this with the moment of the load, we have—

$$\frac{6 \times 68 \times 35.46}{4.136} = \frac{W \times 10 \times 12}{4}$$

$$W = \frac{4 \times 6 \times 68 \times 35.46}{4.136 \times 10 \times 12}$$

$$W = 116.6 \text{ cwt.}$$

If the load had been distributed instead of concentrated in the centre, W would have been twice the above. The factor of safety for a dead load in a girder such as above should be taken at  $\frac{W}{5}$ .—F. E. GAY, Bath.

## CHIPS.

The Maldon Union Rural Sanitary Authority have written to Major Rasche, M.P., and to the County Councilors for the district, requesting them to give the strongest opposition to the proposal to carry the sewage of London by means of a canal through Essex, and to discharge it into the North Sea.

The Senate of Edinburgh University have unanimously resolved to offer the honorary degree of Doctor of Laws to Sir John Fowler and Sir Benjamin Baker, the engineers of the Forth Bridge.

The Derbyshire County Council have decided to take into their own hands the maintenance and repair of all the main roads in the rural districts of Derbyshire, and have sanctioned the division of the county into six districts, authorising the highway committee to appoint a surveyor for each. Over 200 applications were sent in, and the appointments have been made as follows:—Ashbourne division, Mr. J. Millington, of Wirksworth; Chapel-en-le-Frith division, Mr. L. Starkey, of Leeds; Derby division, Mr. W. F. Perry, of Ashby-de-la-Zouch; Chesterfield division, Mr. H. Silcock, of Holmesfield; Belper division, Mr. R. C. Cordon, of Newark; Bakewell division, Mr. D. Roberts, of Bakewell. The salary is £130 per annum for each district except Chesterfield, which, being much larger than the others, carries with it a salary of £150.

At the half-yearly meeting of the Glasgow Barony Parochial Board it was decided to carry out a scheme of asylum extension at Woodlee, at a cost of £32,100. The scheme provides accommodation for 495 beds in the main building, 120 of which will be for hospital cases, and 286 in new chronic blocks, which, with 66 beds already provided, makes a total of 850.

The nineteenth annual soirée and concert of the Edinburgh joiners took place on Friday night in the Masonic Hall in that city, under the presidency of Bailie Walcot.

On Tuesday, the 24th ulto., Mr. J. T. Harrison, M.Inst.C.E., an inspector of the Local Government Board, held an inquiry at the Castle in Leicester with respect to the application of the Billesdon Union Rural Sanitary Authority to borrow £6,203, for works of street improvement and storm drains. The money intended to be spent in making the storm drains is £1,266; and for street improvements, £4,937. Mr. J. B. Everard, M.Inst.C.E., of Leicester, produced plans and explained the former, and Mr. William F. Ault, assistant surveyor to the board, produced plans and gave evidence as to street improvements. There was no opposition.

The United Asbestos Company, Limited, have removed from Queen Victoria-street to more commodious premises at Dock House, Billiter-street, London, E.C., lately in the occupation of the East and West India Dock Company.

The Coventry school board have adopted plans by Messrs. G. and I. Steine, of that city, for new schools at Earlsdon.

## LEGAL INTELLIGENCE.

IN RE W. H. GIBBS.—(Sittings in Bankruptcy, Feb. 28, before Mr. Registrar Brougham.)—This was an application for an order of discharge by William Henry Gibbs, formerly carrying on business as a builder at West Kensington-terrace. The failure occurred in July last, the liabilities being returned in the statement of affairs at £13,941, with an estimated surplus in assets subject to realisation. The bankrupt commenced business in the year 1872 as an engineer, and in 1876 started as a builder on the Cedars Estate, West Kensington, in partnership with another. That business was carried on successfully until 1882, when the partnership expired. The capital of the firm at that time consisted of plant, stock, house property, and building estates amounting to about £100,000, and the bankrupt and his partner converted two-thirds of their business into a limited company, which ultimately went into liquidation. The bankrupt attributed his failure to losses and liabilities arising out of the insolvency of the company, and particularly to liabilities under personal covenants in mortgages; also to his inability to realise his properties in time to satisfy pressing creditors. The only matter reported on by the official receiver as an offence was the insufficiency of the books. On this point the bankrupt was examined by his counsel, and gave some details with reference to the books used in the business, and the documents which he had preserved. He also stated that he had employed an accountant to keep his books. His Honour granted the discharge, subject to a nominal suspension of three weeks.

IN RE C. KILLINGBACK.—A petition for a receiving order has been presented on behalf of Charles Killingback, contractor, of St. James's-street and elsewhere, Camden Town, and of Lee, Kent. The debts, secured and unsecured, are returned at £18,600, and assets between £2,000 and £3,000. Mr. Registrar Linklater made the usual receiving order. The debtor has a contract under the London County Council for the construction of sewers at Lee. Adjudication of bankruptcy was also consented to.

LIABILITY FOR REBUILDING PARTY-WALL.—WILLIAMS v. BULL.—In the Queen's Bench Division, last week, an action of trespass for interfering with the external wall of the plaintiff's house was tried. The trespass consisted in cutting into the plaintiff's wall and building a house against and upon it. The facts of the case raised an interesting question under the Metropolitan Building Act, 18 and 19 Vict. c. 122. In 1884, the plaintiff served on the defendant a notice under the Metropolitan Building Act that he intended to pull down and rebuild the party-wall then existing between the houses of the plaintiff and defendant, and in pursuance of that notice he pulled down the wall. The plaintiff then rebuilt the wall, partly on his own and partly on the defendant's land, to a greater height than the defendant's house. In February, 1885, the defendant served on the plaintiff a party-wall notice, and in pursuance of that notice he pulled down his own house, erected a new house, raising it to a greater height, and for that purpose cut into and used the external wall which had been previously raised by the plaintiff. The wall was built for half its thickness upon land of the defendant's, and it was therefore contended on his behalf that it was a party-wall. The plaintiff, on the other hand, contended that it was an external wall, and the defendant was not entitled to make use of it without paying for the portion of the wall so cut into and used by him.—Mr. Burn, for the plaintiff, argued that the wall in question, so far as it did not separate buildings, was an external wall and not a party-wall; that the provisions of part 3 of the Metropolitan Building Act did not apply in the absence of a notice by the defendant under the Act specifying the wall the defendant cut into; that a wall might be a party wall for some of its height, and above that the property of the adjoining owner ("Weston v. Arnold," L. R. 8. Ch. App. 1084; "Knight v. Pursell," 11, Ch. D. 412). The defendant had no further rights than were given by the Metropolitan Building Act, the effect of which was to limit the right of owners in the interests of the public ("Standard Bank v. Stokes," 9, Ch. D., 68). Whether the wall was half on the land of the defendant was immaterial, for the external wall was by statute for the purposes of the present case the property of the plaintiff (14 Geo. IV. c. 78, section 41; 7 and 8 Vict. c. 84, section 33). Mr. Morton Smith, for the defendant, argued that the case was covered by sections 84 and 93 of the Metropolitan Building Act (18 and 19 Vict. c. 122). The adjoining owner is only liable for expenses incurred by the building owner upon his requisition. When a party wall, which is not defective, is pulled down and heightened, the building owner must incur all the expense. Mr. Justice Mathew, in giving judgment for the defendant, said he could not find any grounds of the liability for which the plaintiff had contended. The sections of the earlier statutes referred to had been repealed, and were not incorporated in the Metropolitan Building Act. Under

the Building Act the whole measure of liability was that where any building owner had incurred any expenses on the requisition of the adjoining owner, the adjoining owner making such requisition should be liable for all such expenses. To say that the expenses were not to be borne by the building owner seemed to be supplying in the Building Act what was not there. Judgment for defendant with costs.

### STAINED GLASS.

**DEWSBURY TOWN HALL.**—A stained-glass window has just been placed in the vestibule in commemoration of certain public works, &c., in which Mr. John Tweedale, who was mayor of Dewsbury in 1865, was interested, more especially in respect to the Dewsbury and Heckmondwike Waterworks, of which he was the originator. The upper portion of the window contains a female figure as representative of Science, and in the base is a picture of Dunford Bridge Reservoir. The work is from the studio of Messrs. Powell Bros., of Park-square, Leeds.

**ROCHESTER.**—On Monday, the 17th ult., water was tapped at the well of the Mid-Kent Water Company at Lower Halling, near Rochester. The well was started last July, and was only dug 50ft. to chalk water level, then bored for 315ft., making a total depth from surface of 365ft. The geological formations passed through were, from the top 140ft. of chalk, a thin layer of rock, 220ft. of gault, a layer of rock 26in. thick, into the lower greensand, when water rose up the lining tubes immediately to within 3ft. of the surface, standing 13ft. in the dug well. It is estimated that the yield is about 25,000gals. per hour at present. The bore-hole is lined with 15in. diameter wrought iron lap welded lining tubes, screwed together in wrought-iron sockets. Mr. Richard Batchelor, of Chatham, was the contractor. The engineers are Messrs. W. Russ and A. F. Bowker.

### CHIPS.

Various additions of carved furniture have recently been made to several of the churches in Folkestone, the cost being borne by the late Miss Phillips, of Leamington, and the work carried out by Mr. H. Bowen, of Tavistock-street, Leamington. These have included the erection in St. Peter's Church of a carved oak pulpit, choir stalls and sedilia, designed by Mr. S. Slingby Stallwood, of Reading, formerly of Folkestone, and oak panelling with canopies around the chancel; a pulpit, in teak, carved and full of tracery, designed by the late Mr. W. W. Cundall, of Leamington, at Trinity Church; three elaborately-carved and traceried screens, now in course of construction, for the parish church; a carved oak rood beam and screen for St. Michael's Church, Folkestone, from designs by Messrs. Bodley and Garner; and a priest's reading-desk, in oak, for the new chapel at St. Andrew's Home, designed by Mr. Ewan Christian.

At a meeting of the Architectural Section of the Glasgow Philosophical Society, held on Tuesday evening, Mr. J. Thomson, president, in the chair, Mr. W. Leiper read a paper on the subject, "Notes on some Italian Towns," with lantern illustrations.

The town council of Leicester have decided to erect a refuse destructor with chimney shaft 160ft. high, in Upper Charnwood and Needham-streets, in accordance with plans prepared by the borough surveyor, Mr. Edward G. Mawbey.

A group of police-station buildings is to be built at Newhaven, at a cost of £1,500, from plans by Mr. Henry Card, of Lewes, county surveyor of Sussex. Mr. G. Chapman, of Newhaven, is the contractor.

A new assembly hall has been erected at Capland-street, N.W., and special attention has been paid to the ventilation, the extraction of the vitiated air being effected by the latest improved form of Boyle's self-acting air-pump ventilator.

The city council of Birmingham have adopted a report by a committee, recommending that an external corridor, carried on iron brackets, and 98ft. in length, be made from the council chamber to the Art Gallery, and that a cloak-room be provided to the same building, in accordance with plans prepared by the city surveyor, at a total estimated cost of £2,500.

The work of repaving the town of East Dereham has just been completed by the contractor, Mr. W. D. Hubbard, of East Dereham, the material used being Imperial stone paving. In addition to this, granite channelling has been laid to the principal streets, the total cost being about £1,900. The works were carried out under the directions of the surveyor, Mr. F. W. Skipper, of East Dereham, and Opie-street, Norwich.

It is proposed to erect a church at Gateshead as a memorial of the late Bishop Lightfoot. A competition of local architects has been arranged.

## Our Office Table.

THE architects of Scotland are by no means satisfied with the reply given by the Council of the Royal Scottish Academy to their memorial to the Queen against the granting of a supplementary charter to that body. At the meeting on Monday of the Edinburgh Town Council a letter by Mr. Robert Strathern, W.S., who is acting for the architects, was read, in which he said:—"On behalf of my constituents, I hope that the Council will not assume that the architects admit the conclusions of the memorial of the Royal Scottish Academy, lodged by way of answer to the architects' petition. The architects have a most complete answer to the memorial, which will be presented at the proper time and in the proper place. In the meantime, all I need further say is that the memorial contains many statements which are not consistent with fact." The letter was sent without comment to the Lord Provost's Committee.

MESSRS. SPON have just issued Macfarlane's "Facilegraph," a sketch-book composed of thin paper sheets, through which ruled lines drawn on a card may be seen by the draughtsman, so that curves, circles, and right angles may be used as a guide in freehand delineation somewhat after the method already familiar in the use of ruled scale paper, but avoiding the objection of the lines being actually set out on the paper itself. The aim of the "Facilegraph" is to enable the artist to secure a mechanical accuracy without the aid of drawing instruments, and for technical students advantages are claimed for it by the publishers as an exercise book for the engineering, mathematical, and kindred classes, while it may be advantageously used for the making of synopses, tables, &c., and even for the writing of arithmetical exercises, in which the use of it has, the author thinks, a considerable educative value in training the student's faculties to ideas of order and symmetrical arrangement. Leading-strings of this character, however, are little calculated to educate the eye or enable the user to master a sense of proportion and value of scale.

At the meeting of the Liverpool County Council yesterday, the finance committee recommended the acceptance of the offer made by Mr. P. H. Rathbone, to complete, at his own cost, the bas-reliefs of the four remaining panels on the south front of St. George's Hall, in accordance with the designs of Mr. Stirling Lee, sculptor, on condition that the whole series of six panels should remain in position for at least five years, the council being at liberty to remove them after that time. An animated discussion took place, but an amendment declaring that the acceptance of the offer would be highly inconsistent, was rejected by 15 to 28, and Mr. Rathbone's offer was accepted.

An approximate return has just been submitted to the members of the London County Council by their engineering staff showing the comparative cost of providing access to the proposed Blackwall tunnel (1) by means of inclined approaches and (2) by means of hydraulic lifts with an approach road. The estimate is for the Middlesex side of the river and for one tunnel 22ft inside diameter. The first cost of an inclined approach is estimated at £250,000, and 36 years' maintenance and lighting at £39,000, making a total of £289,000. The alternative estimate, for approach road, with six lifts for vehicles and four for pedestrians, is £250,000, making, with £309,600 for 36 years' maintenance, a total of £559,600. A lower estimate is given for a similar arrangement, with only four lifts for vehicles, the first cost being £170,000, and the maintenance £216,000—total, £386,000. In view of the proposal to substitute a ferry for the suggested tunnel, a return on the working of the free ferry at Woolwich has been prepared by direction of the London County Council. The total cost of the ferry was £128,451; the cost of maintenance and working for the six months to December 31 last £5,177; the approximate number of passengers, &c., for that period giving an average of 8,865 passengers and 382 vehicles a day.

"METHOD IN ART" was the subject of an address given to the Edinburgh Art Students' Association on Saturday night by Mr. D. W. Stevenson, R.S.A., in the Scottish National Portrait Gallery. Mr. Allan Stewart presided.

Mr. Stevenson urged upon his hearers the necessity of a more methodical manner of commencing, proceeding with, and finishing their work. Sir Joshua Reynolds said "rules are fetters only to men of no genius," and he feared that this truth was not sufficiently valued. Too little attention to method characterised the works of young artists of to-day. No work should be attempted until the artist was inspired by an idea. The happy results of a work begun haphazard by a master seemed to have a vague and subtle charm for the young, and thus led them to underrate the value of method. In all the other arts a strict attention to method was necessary. So in painting and sculpture, the despoiler of method must inevitably be defeated. Students had too great an aversion to any assistance in their art which was mechanical, and this, with the want of a clear idea and fixed purpose, seemed to him to constitute the greatest of the faults of the works of young artists. Some might say that labouring out a work necessitated a cold-blooded result and the evaporation of all fire and energy; but this puerile idea was quite untenable when we considered the labour bestowed on their works by masters not in painting and sculpture alone, but in music and literature.

THE British Consul in Rome, in a recent report, refers to the building crisis in that city, and endeavours to answer two questions—first, whether the crisis has reached its climax; and, second, what its immediate consequences will be. Official statistics show that £11,000,000 sterling of private capital was invested in building in Rome in the six years ending with March, 1888. The larger part of this amount was supplied by mortgage banks on the security of the land and houses. The crisis came in 1887; large stocks of building materials remained on hand, the sale of building land was suddenly checked, and in the less favourably situated quarters underwent an enormous depreciation. Between 1882 and 1887, when the building fever was at its height, rents increased enormously, and even now are much higher than in any other Italian city, except Naples. Owing, however, to the crisis, the market value of house property is low. The population of the city on June 30 last year was 407,936, excluding a considerable floating population.

THE twenty-fifth annual report of the trustees of the Peabody Donation Fund states that the net gain of the year, from rents and interest, has been £29,607 12s. The sum given and bequeathed by Mr. Peabody was, in all, £500,000; to which has been added money received for rent and interest, £494,789 19s. 9d., making the total fund on the 31st December last £994,789 19s. 9d. Of the £390,000 borrowed of the Public Works Loan Commissioners and others, the trustees have paid off £148,666 13s. 4d., leaving a balance unpaid of £241,333 6s. 8d. Within the past year the trustees have expended on land and buildings £1,561 17s. 9d., making the total expenditure to the end of 1889 £1,233,845 17s. 8d. Up to the end of the year, the trustees have provided for the artisan and labouring poor of London 11,275 rooms, besides bath-rooms, laundries, and wash-houses, occupied by 20,374 persons. The rooms comprise 5,071 separate dwellings, say 76 of four rooms, 1,790 of three rooms, 2,396 of two rooms, and 809 of one room.

After opening the Forth Bridge on Tuesday, the Prince of Wales announced that the Queen had conferred baronetcies upon Mr. M. W. Thompson, the Chairman of the Midland Railway and of the Forth Bridge Railway, and Sir John Fowler, K.C.M.G., the principal engineer of the bridge; and knight-hoods upon Mr. Benjamin Baker, the joint-engineer, and Mr. William Arrol, the contractor. Sir Benjamin Baker, K.C.M.G., has been consulted during the past 23 years in the construction of many important bridges in all parts of the world. He was also consulting engineer to the late Metropolitan Board of Works for several years. Sir William Arrol was apprenticed to a Paisley blacksmith at the age of thirteen. He became foreman of the bridge and boiler departments in the works of Messrs. Laidlaw and Sons, of Glasgow and Edinburgh. Twenty years ago, with £85 which he had saved, he started in business for himself as a contractor and repairing engineer. Within three years he received important contracts for iron bridges on the Glasgow, Hamilton, and Bothwell Railway, and for a bridge over the Clyde near the Glasgow Station of the Caledonian Railway. He was also engaged upon the reconstruction of the Tay Bridge.

## MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Surveyors' Institution. "Betterments," by T. W. Wheeler, Q.C. 8 p.m.

TUESDAY.—Society of Architects. Society of Arts. "The Claims of the British School of Painting to a Thorough Representation in the National Gallery," by Jas. Orrock, R.I. 8 p.m.

## WAGES MOVEMENTS.

KENT.—BRICKMAKERS' BARGEMEN.—The barge-men employed by the Kentish brickmakers have issued a demand for increased freightage. The masters have determined not to pay the increase, but to close their brickfields first.

MANCHESTER.—At a meeting of the Bricklayers' Joint Societies, Manchester, Salford, and district, it has been unanimously resolved to petition the employers for an advance of wages from 8½d. to 9d. per hour, and also for a code of working rules.

MERTHYR.—The majority of the masters have consented to grant the men's amended terms of an advance of a halfpenny per hour all round, so that the strike is virtually at an end.

NEWCASTLE-ON-TYNE.—At an influential meeting of the builders and contractors, held on Tuesday afternoon in Mr. Walter Scott's office, it was unanimously resolved to refuse the demand of the bricklayers' labourers for an advance of ½d. per hour, they having had a substantial increase of their wages only about four months ago.

Dr. Waldstein writes from Athens that the excavations of Mr. Cavvadias at Lycosura last summer have resulted in the discovery of the fragments of the group of Demeter and Despna (Persephone), described by Pausanias (Arcadia VIII., 37) as he saw them in the Temple of Despna, the statues and the throne on which they sat being of one piece of stone, carved by Demophon.

The Widnes local board met on Tuesday to consider the 167 applications which had been sent in for the post of surveyor to the board; the situation is worth £250 a year. A memorial was read from a public meeting of ratepayers asking the board to reappoint Mr. Thomas Higginson, who was recently requested by the board to resign the post of surveyor. The memorial pointed out that Mr. Higginson had discharged his duties faithfully, and had served the township well for fifteen years. It was pointed out, however, that the board could not rescind its past resolution without notice of motion, and ultimately it was decided to refer the applications to a committee on the understanding that Mr. Higginson should be one of the half-dozen applicants to come before the board for selection.

The will of Mr. Stephen Stiles, late of 69, Richmond-road, Dalston, and of 8, Cecil-square, Margate, retired builder, who died on December 16th last, has been proved, the value of the personal estate amounting to upwards of £28,000.

The main roads committee of the Cheshire County Council held a special meeting at Crewe last week, to select four road inspectors for the county, the salary attached to the office being £200 a year. The Cheshire County Council recently decided to take over the oversight and repair of their own main roads, a work which had for many years been carried out by various highway boards. There were no fewer than 454 applications. These were first reduced to 13, and out of these the following received the majority of votes and were elected:—Messrs. Linnell, Chester; William Holland, Chester; James T. Boyd, Halifax; and Perman, More, near Chester.

## CHIPS.

It is proposed to restore the exquisite Lady-chapel of Gloucester Cathedral, which is rapidly falling into a ruinous condition, at a cost of £10,000, towards which Dean Spence has promised to contribute £1,000.

At the last meeting of the Aston Manor local board they unanimously resolved to increase the salary of Mr. W. A. Davies, A.M.I.C.E., their engineer and surveyor, £50 per annum.

The new organ gallery at Christ Church, Bristol, is to be decorated with a series of eight carved panels. Two of these have just been fixed in position. One of them represents St. Cecilia seated at the organ attended by St. Urban. This has been given to the church in memory of the late Mr. R. Benson. The other is a fine group illustrating the shepherds and the herald angels. This forms the centre or principal panel. Both panels are the work of Mr. George Houghton, of the Society of Bristol Sculptors.

Holloway's Ointment.—Go where you may, persons will be found who have a ready word of praise for this Ointment. For chaps, chafes, scalds, bruises, and sprains, it is an invaluable remedy; for bad legs, bad breasts, and piles, it may be confidently relied upon for effecting a sound and permanent cure.
